# **SOURCES**RESOURCES ABSTRACTS

VOLUME 24, NUMBER 11 NOVEMBER 1991

W91-10469 -- W91-11600 CODEN: SWRABW **S** ELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Geological Survey, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Water Resources Division, U.S. Geological Survey, MS 425, Reston, VA 22092. The SWRA JOURNAL is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are: Journal only, \$170.00, Journal and Annual Indexes, \$200.00; Indexes only, \$80.00. Other Addresses, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

# SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Geological Survey U.S. Department of the Interior

VOLUME 24, NUMBER 11 NOVEMBER 1991

W91-10469 -- W91-11600

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

#### PREFACE

S elected Water Resources Austracts, journal, includes abstracts of current and earlier reports, and elected Water Resources Abstracts, a monthly pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the Water Resources Thesaurus. The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientists, engineers, and managers as one of several services of the Water Resources Scientific Information Center. The cumulative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE WATER RESOURCES SCIENTIFIC INFORMATION CENTER DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

Water Resources Scientific Information Center U.S. Geological Survey MS 425 National Center Reston, VA 22092

#### CONTENTS

#### SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiration; Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentation; Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impaired Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agriculture.

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water of Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Waste Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Quality Control

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharing, Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact of Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication.

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechanics and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Grants, Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publication and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

Arid and semiarid areas have some hydrological features that make the modeling of rainfall-runoff processes difficult, such as the acute scarcity of precipitation and streamflow data, and the great rainfall variability. Precipitation and discharge have been measured for several years in two small forested catchments located in the Mediterranean area of Spain, where water fluxes have been conarea of Spain, where water fluxes have been considered as a major aspect of vegetation growth and sustainability as well as a vector for nutrient transport to and across the ecosystem. Actual evapotranspiration has been calculated as the difference between annual precipitation and discharge. Results show that: (1) most of the precipitation is evaporated rather than lost by streamflow, even in the most humid years: (2) there is a high interanevaporated rather than lost by streamflow, even in most humid years; (2) there is a high interannual variability both in discharge and evapotranspiration; and (3) annual evapotranspiration correlates significantly with annual precipitation, in contrast to the constancy of annual evaporation in catchments of wet, colder climates. Finally, a simple expression has been proposed in order to calculate annual actual evaporation from the ratio of precipitation to potential evapotranspiration. This expression uses a derived exponent which takes into account the characteristics of individual catchments. (Author's abstract) catchments. (Author's abstract) W91-10963

Descriptors: \*Catchment areas, \*Hydrologic models, \*Model studies, \*Probability distribution, \*Rainfall-runoff relationships, \*Runoff forecasting, \*Watersheds, Reservoir storage.

The spawning of a plethora of catchment models and spawning or a pietnora of catchment models of increasing and arbitrary complexity has been driven by the need for a more accurate representation of catchment response. The probability-distributed catchment model, as originally proposed by Moore & Clark in 1981, was re-examined from a maximum statistical entropy vianaging. The distributions of the control of th aximum statistical entropy viewpoint. The distri-

bution of water within a catchment was treated as a problem of statistical inference and resolved using an entropy maximization technique. A simple trunoff generating mechanism was employed, which, together with the catchment mass balance equation, yields a catchment model involving just equation, yields a catchment model involving just one dynamic parameter, y, and two constants, k and lambda. The parameter y determines the temporal variation of catchment storage V and runoff q. The runoff q is nonlinearly related to V through q = k(1-(lambda)yV), where y provides the nonlinear departure from the simple linear reservoir q=kV. (Author's abstract) W91-10965

DYNAMIC-STOCHASTIC MODELS OF RAIN-FALL AND SNOWMELT RUNOFF FORMA-TION.

Akademiya Nauk SSSR, Moscow. Inst. Vodnykh

L. S. Kuchment, and A. N. Gelfan. Hydrological Sciences Journal HSJODN, Vol. 36, No. 2, p 153-169, April 1991. 12 fig, 2 tab, 13 ref.

Descriptors: \*Flood forecasting, \*Flood frequency, \*Hydrologic models, \*Model studies, \*Rainfall-runoff relationships, \*Snowmelt, \*Stochastic models, Dynamic programming, Maximum probable floods, Monte Carlo method, Numerical analysis, Rainfall, Soviet Union

In many cases observed runoff data are too scarce In many cases onserved runor data are too scarce or nonhomogeneous to determine flood frequen-cies with sufficient reliability using statistical anal-ysis of discharge series. Possibilities for the devel-opment of dynamic-stochastic models of runoff formation with random inputs have been exam formation with random inputs have been examined.

Two models were investigated: the first allows the calculation of the statistical distribution of the maximum discharges of rainfall floods, and the second the statistical distribution of snowmelt volumes.

The rainfall flood formation model was applied to the Coloragin being in the LISES which was the coloragin being the the Golovesnia basin in the USSR, which was schematized as a series of four rectangular reaches each described by the kinematic wave equations and numerically integrated. Most of the parameters were determined from observed data. Runoff hy-drographs for 380 seasons (541 floods) were simudrographs for 380 seasons (541 floods) were simulated, taking into account correlation between input values, and satisfactory agreement was found between the observed and calculated exceedance probabilities. The snowmelt runoff formation model used meteorological inputs generated by the Monte Carlo method and physically-based models for the transformation of input data into runoff. Model verification was carried out for the Sosna River basin in the USSR, characterized by a large variability of groupment runoff, infiltration, and variability of snowmelt runoff, infiltration, and frozen soils. Numerical experiments on the estimafrozen soils. Numerical experiments on the estima-tion of the sensitivity of model-computed results to changes of the model parameters showed that re-sults largely depend on the saturated hydraulic conductivity and an empirical parameter. It was concluded that application of the Monte Carlo method combined with numerical methods of solv-ing differential equations describing dynamic proc-esses in hydrological systems leads to a substantial growth in the number of calculations; however, the increased capabilities of modern computers make this restriction less important. DYNAMIC SIMULATION MODEL OF VERTI-CAL INFILTRATION OF WATER IN SOIL. Gosudarstvennyi Gidrologicheskii Inst., Leningrad

V. Y. Grigorjev, and L. Iritz. Hydrological Sciences Journal HSJODN, Vol. 36, No. 2, p 171-179, April 1991. 3 fig, 1 tab, 18 ref.

Descriptors: \*Hydrologic models, \*Infiltration, \*Model studies, \*Rainfall forecasting, \*Rainfall-runoff relationships, \*Soil water, Aeration zone,

Excess rainfall, Hydraulic gradient, Rainfall rate, Soil profiles, Storm seepage, Surface runoff.

One of the most important problems of hydrological forecasting is to obtain a reliable estimation of effective rain. Infiltration is one of the variables which greatly influences the partitioning of rainfall into surface runoff and subsurface flow. An infliration model has been developed which describes the unsaturated zone as a multilayer system. For the unsaturated zone as a multilayer system. For this purpose, a relationship previously developed for total hydraulic potential versus soil moisture content has been used. The model contains a system of ordinary differential equations for describing soil moisture movement, and it can be scriong soil moisture movement, and it can be interpreted as an aggregated simulation model with lumped parameters. The model was used to measure the dependence of computed excess rain on the homogeneity/inhomogeneity of the soil profile and on the number/thickness of soil layers. With a given rainfall rate, excess rainfall was simulated on unlayered and layered homogeneous soil profiles. The infiltration was stabilized at different levels for 1.5 h in all three cases but the number/thickness of 1.5 hi all three cases but the number/thickness of layers strongly affected the calculated volume of excess rainfall. Excess rainfall appeared first on the profile divided into a maximum of ten layers and last on homogeneous soil. The excess rain on average for a soil with five layers is twice as high as on the unlayered soil, and 2.5 times higher on ten layers of soil than on five. With the rainfall rate, excess rainfall was simulated on a homogeneous and an inhomogeneous soil profile. In the case of the inhomogeneous profile, the second layer in the unsaturated zone had low conductivity. The excess rainfall on the inhomogeneous profile turned out to unsaturated zone had low conductivity. The excess rainfall on the inhomogeneous profile turned out to be twice as high as on the homogeneous one. With an increased number of layers, the model has a finer control over the soil moisture redistribution and hydraulic gradients. As a consequence, the gradient profile becomes 'smoother' and the infiltration rate decreases (the rainfall excess increases). W91-10968

VARIATION OF MOISTURE CONDITIONS IN

CHINA DURING THE LAST 2000 YEARS.
State Univ. of New York at Stony Brook. Inst. for Terrestrial and Planetary Atmospheres.

G. Gong, and S. Hameed. G. Gong, and S. Hameed. International Journal of Climatology UCLEU, Vol. 11, No. 3, p 271-283, April 1991. 7 fig. 3 tab, 20 ref. CO2 Research Division, Office of Basic Energy, US Department of Energy Grant DEFG0285ER60314A007.

Descriptors: \*China, \*Climatic changes, \*Climatology, Climatic data, Climatic zones, Drought, Floods, Meteorological data, Moisture, Precipita-

Utilizing more than 50,000 reports of droughts and floods found in local records, the history of moisture conditions in eastern China has been reconstructed for the last 2000 years. The area studied extends eastward of Gansu province and is situated between Inner Mongolia in the north and Zhejiang in the south. Separate analyses were made for the semi-arid, semi-wet, and wet subdivisions of this area. It was possible to develop moisture indices with a time resolution of 5 years in each subregion. The time series of the moisture index for the semi-The time series of the moisture index for the semi-wet area extends over the period AD 1-1950, while for the other two subregions the period covered is AD 251-1950. Each of the climatic subdivisions was found to undergo prolonged periods of dry-ness and wetness. The frequency of alternation between dry and wet conditions increased from the semi-arid region to the semi-wet regions to the wet region. The variations of moisture conditions in the whole area of eastern China was compared with the known changes in the level of the Caspian Sea. The variations in the two regions were found to be similar on the time-scale of centuries. (Author's abstract) W91-10971

#### METHOD OF COMPILING WATER-MANAGE-MENT BALANCES.

A. S. Reznikovskii. Hydrotechnical Construction HYCOAR, Vol. 24, No. 6, p 411-417, December 1991. 5 ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 6, pp. 38-42, June, 1990.

Descriptors: \*Hydrologic budget, \*Regional analysis, \*Soviet Union, \*Water supply, Regional development, Water consumption, Water resources de-

The Soviet Union has one of the world's greatest total supplies of water, but the specific average runoff (per unit area) is 1.5 times lower than in China, 2 times lower than in the USA, and 2.4 times lower than in France. Adequate supplies of clean water are beginning to become a factor in the continued economic development of certain parts continued economic development of certain parts of the country. To determine the future water supplies available to consumers at given levels of development of the economy, it is necessary to compile water-management balances. The method of compiling water-management balances still remains the subject of discussion by water managers developing water resources schemes. On the basis of the balances for a given region, the region can be divided into non-deficit regions, low-deficit regions, and acutely deficit regions. gions, deficit regions, and acutely deficit regions. Even in well-watered areas of the country, there are some limited areas where provision of water for even existing consumers may be very difficult. The water-management balance consists of two The water-management balance consists of two elements: income (surface and subsurface waters, return and waste waters) and outgo (water consumers, water users, and losses). Each of these elements has a certain annual volume, which varies year by year and has a certain level of reliability. The income portion of the water-management balance includes only that water than can be used ance includes only that water than can be used practically in economic activities. The outgo portion includes both uses of water (e.g., hydropower) and nonreturnable consumption (e.g., evapotranspiration). Ultimately, the water balance can be adjusted to the real situation by determining the sum of all positive and negative differences from a balance throughout the year. If the negative differ-ences are in excess, the region is a deficit region and plans must be made for river regulation, reduction of consumption, or importing water to achieve a balance. (Rochester-PTT) a balance. ( W91-11293

#### HYDROLOGIC SCIENCE: A DISTINCT GEO-SCIENCE

Massachusetts Inst. of Tech., Cambridge. Dept. of Civil Engineering. P. S. Eagleson.

Reviews of Geophysics RVGPB4, Vol. 29, No. 2, p 237-248, May 1991. 8 fig, 1 tab, 9 ref, append.

Descriptors: \*Earth-water interfaces, \*Hydrologic cycle, \*Hydrology, \*Research priorities, \*Reviews, Atmosphere, Data acquisition, Dissolved solids, Ecosystems, Education, Glaciers, Ice, Institutions, Lakes, Oceans, Remote sensing, Rivers,

Hydrologic science deals with the occurrence, distribution, circulation, and properties of water on Earth. It is clearly a multidisciplinary science, as through the hydrologic cycle water is important to and affected by physical, chemical, and biological processes within all the compartments of the Earth system: atmosphere, glaciers and ice sheets, solid earth, rivers, lakes, and oceans. Because of this geophysical ubiquity, and because water is necessary and limiting for life, concern for issues of hydrologic science has been distributed among the traditional geoscience and engineering disciplines. As a result, an infrastructure of hydrologic science (i.e., a clear identity, with supporting educational programs, research grant programs, and research institutions) has not developed, and a coherent understanding of water's role in the planetary-scale behavior of the Earth system is missing. The National Research Council Committee on Opportunities in the Hydrologic Sciences has assessed the status of understanding in the following components of the hydrologic sciences: reservoirs and fluxes of water, space and the Earth's mantle, oceans and atmosphere, the hydrological cycle, the Earth's crust, ice, the flux of sediments and dis-solved solids, and the involvement of biota. Five research areas seem to offer the greatest expected contribution to the understanding of hydrologic science: (1) chemical and biological components of steinless (1) cliential and obligated components of the hydrologic cycle; (2) scaling of dynamic be-havior; (3) land surface-atmosphere interactions; (4) coordinated global-scale observation of water reservoirs and the fluxes of water and energy; and (5) hydrologic effects of human activity. #### CHARACTERIZATION AND SIMULATION OF RAINFALL-RUNOFF RELATIONS FOR HEADWATER BASINS IN WESTERN KING AND SNOHOMISH COUNTIES, WASHING-TON.

Geological Survey, Tacoma, WA. Water Resources Div. R. S. Dinicola.

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 89-4052, 1990. 52p, 21 fig, 7 tab, 21 ref.

Descriptors: \*Computer models, \*Headwaters, \*Model studies, \*Rainfall-runoff relationships, \*Simulation analysis, \*Washington, Computer programs, Flood peak, Performance evaluation, Seasonal variation, Storm runoff.

The characteristics of rainfall-runoff relations were hypothesized for the study area as a whole by using existing information. In undisturbed areas, shallow-subsurface flow from hillslopes mantled with glacial till, groundwater flow from glacial outwash deposits, and saturation overland flow from depressions, stream bottoms, and till-capped hilltops are the important runoff mechanisms. In disturbed, primarily urban areas, Horton overland flow, which is runoff generated from rain falling at a greater rate than the infiltration rate of the soil, is a significant mechanism, along with overland flow from impervious surfaces. These hypothesized characteristics were incorporated into the Hydro-logic Simulation Program-FORTRAN (HSPF) simulation model, and the model was calibrated concurrently at 21 stream gage sites in the study area with hydrologic data from the 1985-86 water years. The calibration resulted in 12 sets of generalized HSPF parameters, one set for each land-segment type with a unique hydrologic response. The generalized parameters can be used with HSPF to simulate runoff from most headwater basins within the study area. The average standard errors of estimate for calibrated streamflow simulation at all 21 sites were 7.9% for annual runoff, 11.2% for winter runoff, 13.11% for spring runoff, 40.1% for summer runoff, 21.7% for storm peak discharge, 21.4% for storm runoff volume, and 42.3% for all daily mean discharges. High flows were simulated more accurately than were low flows. The simulation errors were not large enough to reject the hypothesized rainfall-runoff relations. (Author's abstract) W91-11592

#### ANALYSIS OF PRECIPITATION CHEMISTRY MEASUREMENTS IN SHIMANE, JAPAN.

Shimane Prefectural Inst. of Public Health and Environmental Science, Matsue (Japan). K. Yamaguchi, T. Tatano, F. Tanaka, M. Nakao, and M. Gomyoda.

Atmospheric Environment ATENBP, Vol. 25A, No. 2, p 285-291, 1991. 4 fig, 4 tab, 24 ref.

Descriptors: \*Acid rain, \*Chemistry of precipita-tion, \*Japan, \*Precipitation, Ammonia, Calcium, Coasts, Deposition, Hydrogen ion concentration, Nitrates, Seasalt, Sulfates.

In order to understand the concentration and depo sition levels of the major ions in Shimane, on the Japan Sea coast where precipitation chemistry data Japan Sea coast where precipitation chemistry data are scarce, the precipitation was collected at three sites (Matsue, Cotsu and Masuda) from April 1985 to March 1988. The mean precipitation chemistry was very close to each other except for the seasalt concentration. Masuda showed a halved seasalt contribution compared with the other sites. The volume-weighted annual pH mean at each site ranged from 4.6 to 4.9. Nitrate to SO4(2-) equivalent ratios were in the range of 0.2 and 0.4 throughout the year. Ammonia and calcium species were interpreted to have neutralized approximately 70% of the original sulfuric and nitric acids. cies were interpreted to have neutralized approximately 70% of the original sulfuric and nitric acids. The annual depositions of the major ions in g/sq m/year were as follows: H(+), 0.023-0.037; NH4(+), 0.57-0.68; Ca(2+), 0.51-0.92; S04(2-), 3.29-5.04; NO3(-), 1.20-1.70. These levels were of Japan Environment Agency network results. (Author's abstract)

#### RELATIONSHIP BETWEEN MEAN AND STANDARD DEVIATION IN PRECIPITATION CHEMISTRY MEASUREMENTS EASTERN NORTH AMERICA. ACROSS

Atmospheric Environment Service, Downsview (Ontario).

Atmospheric Environment ATENBP, Vol. 25A, No. 2, p 329-340, 1991. 6 fig, 7 tab, 25 ref.

Descriptors: \*Air pollution, \*Chemistry of precipitation, \*Path of pollutants, \*Precipitation, \*Statistical analysis, \*Statistical methods, Deposition, Ions, Standard deviation, Trend analysis

Characteristics of the distribution of concentration and deposition of major ions in precipitation strongly influence the way in which statistical analyses (for example, trend analysis) are done. It was established that a linear relationship exist between the mean and standard deviation of concentration and deposition of the major ions in precipi-tation for daily, weekly and monthly sampled data. The same relationship also existed for seasonal

#### Precipitation—Group 2B

precipitation-weighted-mean concentration and deposition of both sulfate and nitrate. The transformation, ln(X + sigma), where sigma is a constant that is zero for some ions and non-zero for others, eliminates the dependence of the standard devi-ation on the mean. It is recommended to assess first ation on the mean. It is recommended to assess first the robustness to heteroscedasticity of the statistical technique to be used. If a technique that does not assume homoscendasticity exists, it should be used. If the technique is only robust to small variations in the variance, one should estimate the variation of the variance in the data to be analyzed. If the estimated variation in the variance is too. If the estimated variation in the variance is too large, one should use the transformation ln(X + sigma). (Mertz-PTT) W91-10475

Descriptors: \*Climatology, \*Cloud cover, \*Data interpretation, \*Remote sensing, Albedo, Deserts, International Satellite Cloud Climatology Project, Model studies, Oceans, Seasonal variation, Statisti-cal analysis, Tropical regions, Weather.

The operational data collection phase of the International Satellite Cloud Climatology Project (ISCCP) began in July 1983. Since then, visible and infrared images from an international network of weather satellites have been routinely processed to produce a global cloud climatology. The cloud analysis procedure has three principal parts: cloud detection, radiative model analysis, and statistical analysis. The global annual mean cloud amount over three years is about 60%, the average optical thickness is about nine (equivalent to a spherical over three years is about 60%, the average optical albedo at 0.6 micrometers of about 50%), and the average cloud top temperature is 270 Kelvin. Older climatologies had suggested mean cloud amounts of about 50% and some newer satellite-based analyses obtained similar results. Lower values appear to be caused by incomplete global coverage, especially of southern oceans and less sensitive detection procedures. The classical climate zones are apparent in the variations of climate. mate zones are apparent in the variations of cloud amount. The mid-latitude ocean storm track and amount. The individual coveragence Zone are associated with large cloud amounts. Subtropical deserts are associated with cloud amounts below 40%. The marine stratus regimes are indicated by cloud amounts greater than 60% off the west coasts of continents. Average cloud top heights were about 3.5 km. Diurnal and seasonal variations were noted. Results showed that the average albedo of the clouds was about twice the average albedo of the clouds was about twice the average about of the surface, whereas the average temperature of the clouds was about midway between the average surface temperature and the effective radiating temperature of a clear, water-laden atmosphere. These relationships suggest that the effect of clouds on today's climate is a cooling effect. (Mertz-PTT) W91-10479

COMPARISON OF MICROWAVE TECHNIQUES FOR MEASURING RAINFALL. Applied Research Corp., Landover, MD. A. R. Jameson.

Journal of Applied Meteorology JAMOAX, Vol. 30, No. 1, p 32-54, 1991. 24 fig, 4 tab, 7 ref, append. NASA grants NASS-30303 and NASS-30083.

Descriptors: \*Measuring instruments, \*Microwaves, \*Precipitation rate, \*Rainfall rate, \*Remote sensing, Measurement, Microwave rain estimator, Physical properties, Rainfall, Water measurement.

Many hydrological and other scientific problems require nearly instantaneous measurements of rainfall rate. A large number of techniques were evalufall rate. A large number of techniques were evaluated within a common framework for nearly instantaneous microwave measurements of rainfall and to determine the range of rainfall rates best suited to the various techniques and estimators. The physical basis of a technique as transformed by measurement imperfections of real instruments determines the ultimate performance capability of any microwave rain estimator. While many of the deficits of the measurement process apply to all techniques, the physics behind each estimator differs. A method is presented for objectively evaluating the physical bases of the techniques and for quantifying estimator performance for perfect instruments. These results, which represent the best possible performance expectations, are then temible performance expectations, are then tem pered by standard measurement errors to yield more realistic results. Analysis demonstrates that in general the minimization of rainfall estimate errors over a wide range of rainfall rates requires the simultaneous application of more than one microsimultaneous application of more than one micro-wave rainfall measurement technique. While this theoretical exercise provides useful guidance, measurement realities highlight the need for defini-tive experimental studies. (Author's abstract) W91-10499

Analysis of precipitation events in the St. Louis area, based on pre-event low-level wind flow, was pursued to ascertain the presence of urban effects on fall, winter, and spring precipitation. Data from a circular, dense, raingage network were used to define quadrant (NW, NE, SE, SW) average precipitation. Winds before each event (443 events in 1971-1975) were used to define the urban plume and identify which quadrant was downwind of the city. Results for fall revealed a 17% increase in precipitation downwind of St. Louis and a 13% increase in events with their peak rainfall occurprécipitation downwind of St. Louis and a 13% increase in events with their peak rainfall occurring downwind; both outcomes were statistically significant at the 1% level. The downwind enhancement was greatest when pre-event winds were from the SE, and when average precipitation in the quadrant with the maximum value was either light (<5.1 mm) or quite heavy (>17.9 mm). The fall results agree well with earlier findings for summer rainfall that revealed a 25% increase due to enhancement in isolated airmass showers and during heavier, well-organized con-

vective systems. Winter precipitation indicated little precipitation change downwind of St. Louis. However, when SW pre-event winds existed (a flow often associated with convection), there was a flow often associated with convection), there was a statistically significant downwind increase in winter precipitation; but when pre-event winds were from SE or NW (flows frequently associated with stratiform precipitation), downwind decreases occurred. The number of spring precipitation conditions that maximized downwind of St. Louis was regulated to the converted by whence were stratificantly greater that expected by whence were significantly greater than expected by chance par-ticularly in light (<5.1 mm) events, but the total spring rainfall downwind increased only 4%. There was no suggestion of decreased precipitation in spring or fall. The urban influences to enhance precipitation appeared to be related to precipita-tion conditions with convective processes, and urban influences in more stratiform precipitation situations were negligible. ESTIMATING THE EFFECTS ON THE RE-GIONAL PRECIPITATION CLIMATE IN A SEMIARID REGION CAUSED BY AN ARTIFI-CIAL LAKE USING A MESOSCALE MODEL. Uppsala Univ. (Sweden). Meteorologiska Institu-

L. Enger, and M. Tiernstrom. Journal of Applied Meteorology JAMOAX, Vol. 30, No. 2, p 227-250, February 1991. 20 fig. 4 tab,

Descriptors: \*Artificial lakes, \*Environmental effects, \*Lake-effect precipitation, \*Lakes, \*Meteorology, \*Model studies, \*Precipitation, \*Precipitation mapping, Local precipitation, Mesocale models, Precipitation forecasting, Semiarid climodels, Pre mates, Wind

The effects on the regional precipitation climate by the construction of an artificial lake in a semiarid region were studied. The study was performed using a mesoscale model to identify the larger-scale using a mesoscale moder to identify the arger-scale meteorological conditions when precipitation en-hancement was to be expected and to estimate the amount of precipitation enhancement in such situa-tions. The model results were combined with a tenyear synoptic observations dataset to estimate the mean annual increase in precipitation for the region. The results showed a significant increase in precipitation partly over the artificial lake itself, due to land/sea-breeze type circulations during periods when the large-scale wind is weak and the surface temperature of the sea is higher than that of the surrounding areas, and partly over the mountains north of the area in cases with sufficiently strong southerly winds causing the air to be lifted. Being aware of the uncertainty in the quantitative estimates, it was shown how a combination of mesoscale model sensitivity runs and climatological data can be used to estimate at least the order of magnitude change in precipitation and also identify the areas where it is likely to occur. LABORATORY MEASUREMENTS OF SMALL RAINDROP DISTORTION, PART I: AXIS RATIOS AND FALL BEHAVIOR. Illinois State Water Survey Div., Champaign. Climate and Meteorology Section.
K. V. Beard, R. J. Kubesh, and H. T. Ochs.

A. V. Beard, R. J. Kubesh, and H. T. Ochs. Journal of the Atmospheric Sciences JAHSAK, Vol. 48, No. 5, p 698-710, March 1991. 7 fig, 4 tab, 27 ref. NSF grants ATM 84-19490, 86-01549, and 87-22688.

Descriptors: \*Rain, \*Rainfall, Equilibrium, Laboratory methods, Oscillation, Size, Variability.

The resonant interactions between eddy shedding and drop oscillations for millimeter diameter rain-drops were investigated in a series of laboratory measurements of axis ratio and fall behavior for water drops of diameter = 0.70-1.54 mm. Drops were produced at terminal velocity using a orifice-jet drop generator and allowed to fall several meters so that the initial oscillations (produced designs it benefits) deceased to a scalinglish smallduring jet breakup) decayed to a negligible ampli-tude before the drop shape was recorded using

#### **Group 2B—Precipitation**

stroboscopic photographs. The measured axis ratios had equilibrium values for the smallest sizes, ratios nad equinorium values for the smalest sizes, (diameter = 0.70-0.96 mm), but scattered some-what above equilibrium at intermediate sizes (di-ameter = 1.04-1.29 mm). An order of magnitude larger scatter in axis ratio, extending above and below equilibrium, was found for the largest sizes (1.40 mm) with the average axis ratio being oerow equinorium, was found for the largest sizes (> 1.40 mm) with the average axis ratio being larger than equilibrium. All but the smallest drops displayed a sideways drift varying from 1% of the terminal velocity for diameter = 0.82-11.04 mm, increasing sharply to 6% for diameter = 1.11 mm and gradually lowering to 2% at diameter = 1.54 and gradually lowering to 2% at diameter = 1.54
mm. The observed axis-ratio scatter and fall behavior were generally consistent with simple oscillation and drift responses to various size-dependent
wake configurations as determined from observations of freely falling bodies in liquid tank experiments. The small axis-ratio scatter above equilibrium and maximum in drift corresponds to the onset
of an asymmetric pulsating wake, whereas the
large axis-ratio scatter above and below equilibrium is an apparent axisymmetric oscillation. Sinceum is an apparent axisymmetric oscillation. Since the measured variance in axis ratio is largest for the largest size investigated, resonant oscillations extend far beyond the 1 mm size. Although such a broad coupling between eddy shedding and drop oscillations is not well understood, its existence would explain the shift in axis ratio found for small raindrop sizes using an aircraft optical-array probe and postulated from distrometer-differential reflectivity technique observations. ELECTRICAL AND KINEMATIC STRUCTURE THE STRATIFORM PRECIPITATION GION TRAILING AN OKLAHOMA REGION TR SQUALL LINE.

National Severe Storms Lab., Norman, OK. T. J. Schuur, B. F. Smull, W. D. Rust, and T. C.

Journal of the Atmospheric Sciences JAHSAK, Vol. 48, No. 6, p 825-842, March 15, 1991. 18 fig, 1 tab, 50 ref. NOAA grant NA85RAH05046.

Descriptors: \*Electric fields, \*Meteorology, \*Oklahoma, \*Precipitation, \*Rainfall, \*Squalls, \*Storms, \*Thunderstorms, Clouds, Lightning, Radar, Stratiform clouds, Weather, Weather data

An electric field sounding through the transition zone precipitation minimum that trailed an Oklaho-ma squall line on June 18, 1987 provides informa-tion about the electrical structure within a midaltitude trailing stratiform cloud. A single-Doppler radar analysis concurrent with the flight depicts a kinematic structure dominated by two mesoscale flow regimes previously identified in squall-line systems: a strong midlevel, front-to-rear flow coin-ciding with the stratiform cloud layer and a de-scending rear inflow that sloped from 6.5 km AGL scelectric field magnitude vs height) at the strati-form cloud's trailing edge to 1.5 km AGL at the convective line. Electric field magnitudes as high as 113 kilovolts/m were observed by the electric as 113 kilovolts/m were observed by the electric field sounding, which reveals an electric field structure comparable in magnitude and complexity to structures reported for convective cells of thun-derstorms. The charge regions inferred with an approximation to Gauss' law have charge density magnitudes of 0.2-4.1 nanocoulombs/cubic m and vertical thicknesses of 130-1160 m; these values, too, are comparable to those reported for thunder-storm cells. In agreement with previous studies, an analysis of the lightning data revealed a bipolar cloud-to-ground lightning pattern with positive flashes being relatively more common in the stratiform region. From the analysis, it is concluded that the stratiform region electrical structure may have been advected from the squall line convective cells are the included that the stratiform of the squall line convective cells. as the in-cloud charge regions were primarily found within the front-to-rear flow. Screening layers were found at the lower and upper cloud layers were found at the fower and upper foodule boundaries. In situ microphysical charging also seems to be a possible source of charge in the stratiform region. It is hypothesized that the radar-derived similarities of this system to those previously documented suggests that the newly-docu-mented stratiform electrical structure might also be representative of this type of mesoscale convective system. THREE-DIMENSIONAL SIMULATION OF AIRFLOW AND OROGRAPHIC RAIN OVER THE ISLAND OF HAWAII.

Scripps Institution of Oceanography, La Jolla, CA. K. Ueyoshi, and U. J. Han. Journal of the Meteorological Society of Japan JMSJAU, Vol. 69, No. 1, p 127-152, January 1991. 17 fig, 1 tab, 72 ref. USDA contract no. PSW-88-0006CA and NOAA grant NA86AA-D-CP104.

Descriptors: \*Computer models, \*Hawaii, \*Model studies, \*Orographic precipitation, \*Precipitation, \*Rainfall distribution, \*Simulated rainfall, Airflow, Mountains, Terrain analysis, Vortex.

A three-dimensional mesoscale numerical model was designed with the capability of simulating the airflow and orographically-induced rain in the presence of steep irregular terrain. The model utilizes a fourth-order accurate version of Arakawa's nzes a fourth-order accurate version of Arakawa's potential enstrophy and total energy conserving scheme to improve the simulation of nonlinear aspects of the airflow over steep topography, along with an adiabatic reference atmosphere to adough with an adabatic reference atmosphere to reduce the effects of orographic truncation errors. The precipitation processes are represented by large-scale condensation. The model is applied to the island of Hawaii. The results of a 24-hour simulation indicate the model is generally successful in reproducing leeward eddies depicted in the composite surface airflow patterns. A nondimensional analysis of vortex parameters suggests that sional analysis of vortex parameters suggests that the simulated vortex partern is an atmospheric analog of the Karman vortex street and compares favorably with an observed case of Hawaii vortices. Spatial distribution of simulated rainfall is also generally in good agreement with observations. However, the lack of precipitation in the lowland along the windward as well as leeward coast is apparent. The excess rainfall over the southern peninsula suggests the need for a fire grid mash to apparent. Ine excess raintail over the southern peninsula suggests the need for a finer grid mesh to improve representation of the effects of subgrid-scale mountain forcing. The model was applied to regional climate modeling through the use of large-scale objective analyses. (Author's abstract) W01.10312 W91-10517

ZONAL AVERAGE CLOUD CHARACTERIS-TICS FOR GLOBAL ATMOSPHERIC CHEMIS-TRY MODELLING.

Max-Planck-Inst. fuer Chemie, Mainz (Germany, F.R.). J. Lelieveld, P. J. Crutzen, and H. Rodhe

Available from the National Technical Information Service, Springfield, VA 22161, as N90-12992. Price codes: A04 in paper copy, A01 in microfiche. Report No. CM-76, June 1989. 54p, 10 tab, 60 ref.

Descriptors: \*Atmospheric chemistry, \*Climatology, \*Clouds, \*Distribution patterns, \*Model studies, Air circulation, Atmospheric circulation, Cloud cover, Convection, Mathematical studies.

A zonal average cloud distribution for the lower (approximately 6 km) troposphere was derived from surface observations of cloud occurrence and the average vertical extent of clouds. Assessments of updraft velocities through convective clouds and lifetime estimates of stratiform clouds were used to calculate the average time that air spends in clouds and the time between successive cloud encounters, as a function of latitude and altitude. The inferred cloud data compared well with satellite observations, but not very well with data de-rived from calculations with a general circulation rived from calculations with a general circulation model. For such models more effort has to be devoted to the development of cloud parameterizations in order to produce cloud distributions a needed for global atmospheric chemistry modelling. A. J. Mazzella, D. E. Delorey, K. P. Larson, and P. Dickson.

P. Dickson. Available from the National Technical Information Service, Springfield, VA. 22161, as AD-A215 342. Price codes: A03 in paper copy, A01 in microfiche. Report No. GL-TR-89-0172, June 30, 1989. 22p, 3 fig, 5 tab, 3 ref.

Descriptors: \*Data interpretation, \*Data processing, \*Meteorology, \*Rainfall, Climatic data, Computer programs, Computers, Rain gages.

Data processing and analysis have been performed for 42 individual rainfall measurement stations lo-cated throughout the United States. For most of these stations, the data were recorded for the tness stations, the data were recorded for the entire 10-yr period from January 1970 through December 1979, but data were recorded for a slightly different period for Urbana, and for shorter periods and selected months for San Sebastian (Puerto Rico), Kekaha (Hawaii), and Lalamilo (Hawaii). These data were initially recorded as weighing rain gage measurements, and were converted to one-minute rainfall rates according to previously described procedures. The data were then transferred by tape to the Geophysics Laboratory (GL) for further processing and analysis. The processing and display programs and procedures were initially developed for the GL CYBER system and peripherals, and were adapted and extended for use on one of the GL VAX/VMS systems. Because the tapes were originally created on a VAX/VMS system, this system migration enabled the elimination of the data unpacking process on the CYBER in favor of a simple file copy process on the VAX. Furthermore, the VAX copy process on the VAX. Furthermore, the VAX laser plotters could be used to generate the appropriate size and format plots more easily than the Calcomp drum plotter used by the CYBER. Summary rainfall data were merged with climatologimary rainfall data were merged with climatologi-cal data for each station, to provide a basis for model development of rainfall patterns. Critical rainfall rates for the attenuation of radio wave transmissions were also obtained from the Envi-ronmental Technical Applications Center (ETAC) and were utilized in conjunction with the rainfall rate data to evaluate transmission outage occur-rences for the individual station sites. These critical rates correspond to the climatological conditions appropriate to the individual sites for selected months, and are related to the transmission path lengths through the rainfall zone. (Lantz-PTD) lengths through the rainfall zone. (Lantz-PTT)

CORRELATED OCEANIC AND CONTINENTAL RECORDS DEMONSTRATE PAST CLIMATE AND HYDROLOGY OF NORTH AFRICA (0-140 KA).

Environmental reconstruction of the latest climatic cycle in Africa has been severely limited by the incomplete record, owing primarily to major discontinuities in lacustrine sediments preserved in a predominantly arid climate. Analysis of pollen and dinocysts in a core from the eastern Atlantic (core V22-196; lat 13 degree 50 minutes north, long 18 degrees 57 minutes west) provides the first continuous record of paleoclimate and paleohydrology for the latest climatic cycle. During interglacial intervals, increases in pollen input from humid vegetation zones are correlative with high dinocyst productivity. The data indicates a close coinci-dence of northward extensions of Sudanian and Guinean vegetation zones in North Africa and increases in freshwater input into the Atlantic. Direct evidence indicates positive hydroclimatic phases at 135, 125, 103, 80, 47, and 12-10 ka,

coincident with widespread continental records of high lake levels, that confirm the validity of the U/ Th chronology. (Author's abstract)

HYDROLOGICAL ASPECTS OF THE 1988 DROUGHT IN ILLINOIS, Illinois State Water Survey Div., Champaign. Cli-matology and Meteorology Section. W. M. Wendland.

Water Resources Bulletia WARBAQ, Vol. 26, No. 6, p 913-920, December 1990. 5 fig, 2 tab.

Descriptors: \*Drought, \*Illinois, \*Precipitation, \*Rainfall-runoff relationships, \*Surface-ground-water relations, \*Water deficit, Annual precipitat-tion, Areal precipitation, Attitudes, Drought ef-fects, Hydrologic budget, Lakes, Precipitation in-tensity, Precipitation mapping, Recharge, Rivers,

Drought is a complex mix of the magnitude, dura-tion, and areal extent of a precipitation deficit. In simple terms, a drought exists when water demand simple terms, a drought exists when water demand exceeds supply for an extended period. Drought perception, on the other hand, is also a function of the sensitivity of an activity to water availability, the time of year, and perhaps, the magnitude of the deficit relative to some 'expected' value. Drought has been evaluated in terms of the magnitude and has been evaluated in terms of the magnitude and duration of the 1988 spring and summer precipita-tion shortfall in Illinois, and various components of the hydrologic budget, both surface and sub-sur-face (i.e., soil moisture, river flow, lakes and rivers, and groundwater). The response time of some of these components was investigated, relative to the time of precipitation. Lags were noted in the re-sponse of soil moisture, lakes, and groundwater to receipitation. These lags were not uniform, nor are sponse of soil moisture, lakes, and groundwater to precipitation. These lags were not uniform, nor are were they constant through time. These unconformities in the response to precipitation occurred because recharge to any of these components depended in part on their sensitivity to change, the antecedent conditions, and the magnitude and rate of the renewing precipitation. ESTIMATION OF THE MEAN FIELD BIAS OF

ESTIMATION OF THE MEAN FIELD BIAS OF RADAR RAINFALL ESTIMATES. Princeton Univ., NJ. Dept. of Civil Engineering and Operations Research. J. A. Smith, and W. F. Krajewski. Journal of Applied Meteorology JAMOAX, Vol. 30, No. 4, p 397-412, April 1991. 8 fig. 1 tab, 37 ref,

Descriptors: \*Meteorological data, \*Probable maximum precipitation, \*Radar, \*Rainfall, \*Rainstorms, \*Statistical models, \*Statistics, Data interpretation, Estimating equations, Parameter estimation.

Procedures were developed for estimating the mean field bias of radar rainfall estimates. Mean field bias is modeled as a random process that varies not only from storm to storm but also over varies not only from storm to storm but also over the course of a storm. State estimates of mean field bias are based on hourly raingage data and hourly accumulations of radar rainfall estimates. The pro-cedures were developed for the precipitation proc-essing systems used with products of the Next Generation Weather Radar (NEXRAD) system. Generation Weather Radar (NEARAD) system.

To implement the state estimation procedures, parameters of the bias model must be specified. Likelihood-based procedures were developed for estimating these parameters. A simulation experiment was carried out to assess performance of the parameter estimation procedure. Convergence of parameter estimators is enabled to the cases studied. rameter estimators is rapid for the cases studied, with data from approximately 25 storms, providing parameter estimates of acceptable accuracy. The state estimation procedures were applied to radar and raingage data from the 27 May 1987 storm,

which was centered near the NSSL radar on Norman, Oklahoma. The results highlight depend-ence of the state estimation problem on the param-eter estimation problem. (Author's abstract) W91-10857

USE OF SINGLE-DOPPLER RADAR FOR ESTIMATING MAXIMUM HAILSTONE SIZE.

National Severe Storms Lab., Norman, OK. A. Witt, and S. P. Nelson. Journal of Applied Meteorology JAMOAX, Vol. 30, No. 4, p 425-431, April 1991. 4 fig, 2 tab, 40 ref.

Descriptors: \*Hail, \*Precipitation, \*Radar, \*Rainstorms, \*Remote sensing, Data interpretation, Doppler radar, Estimating equations, Meteorologi-

The relationship between a storm's divergent outflow magnitude at upper levels and maximum hail-stone size was investigated by analyzing single-Doppler radar data for 49 severe hailstorms. Two Doppier radar data for 49 severe natisforms. I wo different techniques were developed for use with single-Doppier radar data to estimate the magnitude of divergent outflows. The developed techniques show considerable skill at estimating the maximum hailstone size produced by a thunderstorm, with the correlation coefficients between the parameters used and maximum hailstone size being as high as 0.89. The data also show that estimates of maximum hailstone size have an 80% chance of being accurate to within + or -1.4 cm.

The developed techniques are computationally simple and should be useful for real-time estimation of the maximum hailstone size likely to be produced by a thunderstorm. (Author's abstract) W91-10858

The Canadian Atlantic Storms Program (CASP) field project was conducted from 15 January to 15 March 1986 over Atlantic Canada in conjunction with the American Genesis of Atlantic Lows Experiment (GALE). The goals of CASP were to begin the process of understanding and eventually better predicting the mesoscale structure of East Coast storms as well as the storms themselves. Coast storms as well as the storms themselves. Conceptual models of the storms have been formulated, the nature of cyclogenesis and the structure of frontal surfaces have been investigated, and precipitation regions and precipitation type transitions have been studied. The storms exhibit an organization similar to that seen elsewhere, although the occurrence of a variety of precipitation types has not been studied extensively before. The geographical setting of the warm Gulf Stream to the south and the cold, often snow-covered, land

represents a unique situation which can sometime assist in rapid storm evolution and it can also result in the establishment of heavy precipitation produ ing regions along coastlines. Numerical weather simulations have been used to better understand simulations have been used to determine understand critical parameters affecting storm behavior and improvements in instrumentation have been made. CASP II will be able to utilize improved observational capabilities. To properly monitor the three-dimensional kinematic and thermodynamic fields over the ocean and ice fields, a dropsonde capabilities. ity utilizing a cross-chain Loran system will be used. Future research activities are needed to better understand the interaction of the storms with surface features such as coastlines and sea ice. (Fish-PTT) W91-10943

SOME UPDATED STATISTICAL ASSESSMENTS OF THE SURFACE TEMPERATURE RESPONSE TO INCREASED GREENHOUSE GASES.

Frankfurt Univ. (Germany, F.R.). Inst. fuer Meteorologie und Geophysik

C. D. Schonwiese, and K. Runge.

International Journal of Climatology IJCLEU, Vol. 11, No. 3, p 237-250, April 1991. 9 fig. 3 tab, 37 ref. German (FRG) Climate Research Pro-gramme (BMFT, project number KF 2012 9).

Descriptors: \*Air temperature, \*Carbon dioxide, \*Climatic changes, \*Climatology, \*Global warming, \*Greenhouse effect, \*Model studies, Atmospheric circulation, Climatic data, El Nino/Southern Oscillation, Meteorological models, Regression analysis. Statistical analysis

An earlier study has analyzed the surface temperature response to increasing atmospheric carbon dioxide (CO2) concentrations based on long-term observational climate time series using multiple regression statistical techniques. These assessments were compared with the results from general circulation model experiments. Recently, improved climate data sets were used, adding ENSO (El climate data sets were used, adding Ensol (E) Mino/Southern Oscillation) forcing to the multiple regression models, the volcanic forcing parameters were improved, and phase shifts of the temperature response to the forcing parameter time series were introduced. In addition, not only CO2 but also 'equivalent' CO2 concentrations were used to accept count for additional greenhouse gases. The signal assessments were based on three different temperature data sets, all forcing parameter time series used, different periods (from 1851-1980), and different filters (3 and 10-year low-pass). The results show that, for the mean Northern Hemisphere surface air temperature, the CO2 doubling extraposurface air temperature, the CO2 doubling extrapo-lation leads to signals (temperature increase) of the order of 2.4-5.4 K, in the 'equivalent' case 2.3-6.1 K. The corresponding mean Southern Hemisphere results are 2.5-4.6 K (CO2 doubling) and 2.9-5.4 K ('equivalent'). The mean global data extrapolations lead to 2.7-4.4 K (CO2 doubling) and 2.9-5.2 K ('equivalent'). The order of magnitude of the statistically assessed CO2 doubling signals (2.7-4.4 K) tically assessed CO2 doubling signals (2.7-4.4 K) agrees very well with climate model intercomparisons made previously. Following this result, the 'industrial' greenhouse-gas-induced surface air temperature signals may also be specified: on a global average, this temperature rise may be of the order of 0.5-0.9 K ('equivalent') with 0.3-0.6 K due to CO2 forcing ('reduced to CO2'). It was concluded that one may derive a possible date of the greenhouse gas signal detection in the observational surface air temperature data based on these latest statistical results. (Fish-PTT) statistical results. (Fish-PTT) W91-10969

CLIMATIC CHANGE AND FUTURE AGRO-CLIMATIC POTENTIAL IN EUROPE.

Descriptors: \*Agriculture, \*Climatic changes, \*Climatology, \*Europe, \*Global warming, \*Greenhouse effect, Air temperature, Carbon dioxide, Computerized maps, Corn, Denmark, England, Finland, Germany, Poland, Russia, Scandinavia, Weather natterns Weather patterns

A study has been performed to evaluate the broad-scale sensitivity of agriculture to climatic change in scale sensitivity of agriculture to climatic change in Europe, using an agroclimatic index, effective tem-perature sum (ETS), to relate temperature patterns to the cultivable limits of grain maize (Zea mays). A computer mapping system for the European region was adopted to map ETS on the basis of both present-day and possible future mean tem-peratures. In this way, changes in climate can be depicted as geographical shifts of the limit of po-tential grain maize cultivation. The results indicate that a mean annual temperature increase of only 1 tentia grain maiaze cultivation. The results indicate that a mean annual temperature increase of only 1 C (within the present-day range of interannual variability) would open up large areas in southern England, the Low Countries, eastern Denmark, northern Germany, and northern Poland to potential tenties authority and northern Poland to potential tenties authority and interest of 4 Countries. northern Germany, and northern Poland to potential maize cultivation. An increase of 4 C would move the limit into central Fennoscandia and northern Russia. These represent rates of northward shift of approximately 200-350 km/C in western Europe and 250-400 km/C in eastern Europe. Comparison of these shifts with those estimated on the basis of general circulation model (GCM) projections of future temperatures suggests that a 1 C warming will be achieved well before the time the global climate responds fully to an equivalent doubling of atmospheric carbon dioxide, possibly as early as 2010. Shifts comparable with those for a 4 C warming are achieved under all the GCM scenarios of doubled CO2, occurring perhaps as soon narios of doubled CO2, occurring perhaps as soon as 2050. The rate of shift of the grain maize limit implied for this (high) emissions scenario is in the order of 150-200 km per decade over the next 70 years, slower than this during the next few decades, but faster thereafter. Such shifts would offer new opportunities for farmers in different regions of northern Europe. However, immediate attention should be directed towards more detailed assessments of crop potential in regions identified as currently marginal for grain maize. (Author's ab-W91-10970

An extension and update has been made of a previ-An extension and update has been made of a previ-ous analysis of spatial and temporal variations in precipitation over England and Wales. In the newest study, the U.K. was divided into nine re-gions of coherent precipitation variability on the basis of our earlier principal components analysis. Daily and monthly time-series were assembled for seven sites within each region, and area-average series and statistics were computed. Correlations were investigated among the sites within each

region, among regions on daily to annual time-scales. Monthly time-series spanning the period 1931-1989 for England and Wales, for Scotland and for Northern Ireland were calculated by fur-ther combining the nine regions. Examination of the intersite variability within the regions confirms that daily rainfall series from individual sites are highly correlated, and therefore that these regions of coherent precipitation variability on daily and longer time scales. Area-average series correlations longer time scales. Area-average series correlations between the seasonal and annual time-series for different regions are strongest for regions that are close together. In particular, the western side of the country correlates more strongly with the west, and likewise for the eastern regions. However, there are only very weak relationships between the regions of England and Wales and those of Scotland. From the regional series constructed, no long-term trends in precipitation were apparent. (Fish-PTT) W91-10973

RELATION OF ATMOSPHERIC CO2 TO TROPICAL SEA AND AIR TEMPERATURES AND PRECIPITATION. National Oceanic and Atmospheric Administra-tion, Silver Spring, MD. Air Resources Lab. W. P. Elliott, J. K. Angell, and K. W. Thoning. Tellus TELLAL, Vol. 43B, No. 2, p 144-155, April 1991. 5 fig, 5 tab, 21 ref.

Descriptors: \*Air temperature, \*Atmospheric circulation, \*Carbon dioxide, \*Climatic changes, \*Climatology, \*El Nino/Southern Oscillation, \*Marine climates, Alaska, American Samoa, Correlation analysis, Hawaii, Pacific Ocean, Precipitation, South Bola, Teorica poses tion, South Pole, Tropic zone.

Associations between the season-to-season changes in CO2 concentration and the sea-surface tempera-ture in the eastern equatorial Pacific, the tropospheric air temperature, and the precipitation in the tropics have been explored. The CO2 records the tropics have been explored. The CO2 records at Mauna Loa, Hawaii, and the South Pole from the Scripps Institution of Oceanography and the GMCC/NOAA (Geophysical Monitoring for Climate Change/National Oceanic and Atmospheric Administration) program, as well as the GMCC records at Barrow, Alaska, and American Samoa, were used after the annual cycle and the growth due to fossil fuel emission was removed. It was found that the correlation between CO2 aboves. found that the correlation between CO2 changes and each of the other variables changes with time. In particular, the period from about 1968 to about 1978 was the period of highest correlation, which was also the period when the climate variables were best correlated with each other. The air were best correlated with each other. The air temperature and the precipitation were also correlated with CO2 changes as was SST (sea-surface temperature). Also, there are individual seasons when the CO2 changes are much better correlated with the climate variables than at other seasons. Furthermore, El Nino events, while the source of the largest signal in the CO2 record, are by no means the same from one event to the next. These results were interpreted as further confirmation that the apparent effect of SST on the CO2 record comes less from changes in the equatorial eastern comes less from changes in the equatorial eastern Pacific Ocean than from climate changes through-out the globe. Climate effects on the terrestrial biosphere seem a likely source of much of the interannual variation in atmospheric CO2. (Author's abstract)

WATER SUPPLY IMPLICATION OF CLI-MATE CHANGE IN WESTERN NORTH AMERICAN BASINS. Agricultural Research Service, Beltsville, MD.

Agricultural Research Service, Densylvas, Mar-Hydrology Lab.

A. Rango, and V. Van Katwijk.

IN: International and Transboundary Water Re-sources Issues. American Water Resources Asso-ciation, Bethesda, Maryland, 1990. p 577-586, 7 fig.

Descriptors: \*Climatic changes, \*Climatology, \*Global warming, \*Hydrologic budget, \*North America, \*Water supply, Air temperature, Model studies, Rio Grande Basin, Runoff, Seasonal variation, Snowmelt, Water demand, Water resources

A snowmelt-runoff model and a series of stepwise changes in model variables and parameters have been employed to determine possible hydrologic responses to climate change on western North American basins. The expected increase in mean global air temperature will have a major effect by causing a redistribution of flow with pronounced increases in April and May and decreases in the Summer months. The increase in temperature will also cause a time shift of certain model parameters. Summer months. The increase in temperature will also cause a time shift of certain model parameters which will somewhat reduce the April and May increases in flow and magnify the decreases in the Summer months. It is not well known what kind of changes in precipitation will result from climate change. This study shows, however, that a change in the April 1 snow water equivalent can potentially cause a significant hydrologic response, especially in concert with the temperature increase. For example, on the Rio Grande basin a 3 C increase in temperature in combination with a 25% decrease in April 1 snow water equivalent and a decrease in April 1 snow water equivaent and a 10% decrease in snowmelt season precipitation will cause a 30% decrease in seasonal flow, as well as a 53% increase in April runoff and a 61% decrease in June runoff. Such a response, if widespread, could cause a serious widening of the already existing gap between water supply and water demand in western North America. (See also W91-11003) (Author's abstract)

#### Precipitation—Group 2B

Cryospheric dynamics, particularly relationships and feedback between clouds and the cryosphere when snow cover is forming or dissipating were analyzed, and algorithms and climatologies used in Air Force operational snow and cloud cover prod-ucts were assessed. These objectives have been met, resulting in improvements in snow and cloud met, resutting in improvements in snow and cloud climatologies as well as leading to an increased understanding of: (1) seasonal and inter-annual variations in snow and cloud cover; (2) dynamics of the onset of melt season in arctic regions; (3) performance of Air Force nephanalyses in marginal cryosphere regions; and (4) performance of the Air Force SNODEP model. Project results instability to the project results in-Air Force SNODER model. Project results in-clude: (1) cloud cover in the Arctic Basin has a late May-early June maximum in extent and thickness, followed by a period of less extensive and thinner cover extending into early August. Cloud condi-tions are associated with the distribution of surface ressure and the flow of air into the Basin at the arface and aloft; (2) over arctic lands and sea ice, surface and aloft; (2) over arctic lands and sea ice, the timing and duration of the snow melt season, which strongly influences the surface mobility of personnel and machinery, vary geographically within a year and across the region from year to year; (3) increased spring cloudiness and the onset of the melt season over sea ice coincide, suggesting that both are related to the northward transport of moist air into the Basin by synoptic disturbances, rather than one solely driving the other. Results over arctic lands are less conclusive. Varying conditions of thee snow pack, the surface albedo, the seasonal and latitudinal distributions of solar insolation reaching the top of the atmosphere, are among seasonal and latitudinal distributions of solar insolation reaching the top of the atmosphere, are among the other factors influencing melt; (4) a southward shift in the mid-winter snow line was found over the central United States in the past 50 years; and (5) short-term variability of snow extent was ob-served over the Tibetan Plateau. Despite the cold winter temperatures in this region, the presence of snow cover is strongly precipitation dependent, perhaps more so than in any other part of the world. (Lantz-PTT) W91-11095

Throughfall. bution, Sodium, Sulfates, Throughfall.

The Global Tropospheric Experiment (GTE)-Amazon Boundary Layer (ABLE) study was con-ducted during the wet (April-May) and dry (August-September) seasons of 1987. For each period a continuous record of rainwater and throughfall composition and amount was obtained in a 'terra firme' (nonflooded) rainforest ecosystem in Central Amazonia (Brazil). During the GTE-ABLE 2B campaign, samples were obtained at the Ducke Reserve (2 deg 57 min S, 59 deg 58 min W). All samples were collected from April 1 to May 13 and from August 1 to October 1, and analyzed for Na(+), K(+), Mg(2+), Ca(2+), NH4(+), Cl(-), and SO4(2-), and pH. The rainwater was acidic, with a volume-weighted mean pH of 4.6 for the with a volume-weighted mean pri of 4.5 for the two periods. Rainwater input from the dry period was two times greater for Na(+), Mg(2+), NH4(+), and SO4(2-) and about four times greater for K(+) than rainwater input from the dry wet period. The ionic concentrations in throughfall were higher than those in rainwater, except for NH4(+) during the dry period. This enrichment of throughfall is attributed to the interaction of precipitation with the forest canopy. (Author's ab-W91-11218

The quantitative description of temporal variability in precipitation is critical to an understanding of hydrologic processes. A variety of precipitation simulation methods have been reported. A method of precipitation simulation that incorporates climatological information has been developed. A Markovian-based model was employed to generate temporal sequences of six daily weather types: high pressure, coastal return, maritime tropical return, frontal maritime tropical return, cold frontal overrunning, and warm frontal overrunning, and warm frontal overrunning, and warm frontal overrunning observed statistical relations between weather types and precipitation characteristics. When this method was applied to an area in the Delaware River basin (Pennsylvania/New York), the statistics describing average precipitation, extreme pretics describing average precipitation, extreme pre-cipitation, and drought conditions for simulated precipitation closely matched those of the ob-served data. Potential applications of this weather type precipitation model include climatic change research and modeling of temperature and evapo-transpiration. (Author's abstract)

Values of collision efficiency and scavenging rates for drops interacting with aerosol particles were presented using more accurate flow fields than presented using more accurate flow heats that previous work and for a much greater number of drops than hitherto obtained. All calculations were performed at an ambient temperature of 10 C and atmospheric pressure of 900 mb. Collision efficience. was computed for a drop radius range from 50 500 micrometers, for particle radius from 0.005

to 10 microns, for relative humidity values of 50, 75, 95, and 100%, and for particle density of 1,000, 1,500, 2,000, and 2,500 kg/cu m. In addition the collision efficiency was also calculated for electric charges on the drop and particle, and for an elec-tric field, representative of typical thundercloud values. A rigorous trajectory model was used to-gether with a flux model and comparison is made between them in the overlap size region. Precipita-tion scavenging rates and the percentage of aerosol particles scavenged by precipitation drops de-scribed by Marshall-Palmer size distributions was calculated. Predictions for the two models generalcalculated. Predictions for the two models general-ly agreed to within a factor of two for particle radius <0.8 microns. Collision efficiency values using the trajectory model increased with decreas-ing relative humidity with the increase greatest for the smallest sized drops and particles. The collision efficiency is increased due to electrical forces, since the electrical forces are attractive causing the particle to cross air flow streamlines towards the drop. The effect was greater for smaller drops and particles. Collision efficiency increased with partiparticles. Collision efficiency increased with parti-cle density for the relatively larger particles due to increased particle inertia with an increased likeli-hood of penetrating the air flow streamlines. The percent of scavenged particles is less than 1% under all conditions tested for particle radius <1 micron and is generally of the order of 0.1% or less for the submicrometer aerosol particle frac-tion. There is between about 25 and 30% increase in percentage of particles scaveneed for doubling in percentage of particles scavenged for doubling of the precipitation rate throughout the particle size range due to a similar order mean increase in drop concentration (Geiger-PTT) with precipitation W91-11252

AEROSOL AND HYDROMETEOR CONCENTRATIONS AND THEIR CHEMICAL COMPOSITION DURING WINTER PRECIPITATION ALONG A MOUNTAIN SLOPE; III. SIZE-DIF-FERENTIATED IN-CLOUD SCAVENGING EF-

Eidgenoessische Technische Hochschule, Zurich (Switzerland). Atmospheric Physics Lab. T. Schumann

Atmospheric Environment ATENBP, Vol. 25A, No. 3/4, p 809-824, 1991. 11 fig, 5 tab, 28 ref.

Descriptors: \*Aerosols, \*Chemistry of precipita-tion, \*Cloud chemistry, \*Nucleation, \*Particulate matter, \*Precipitation scavenging, Ammonia, Cloud physics, Condensation, Deposition, Nitrates,

During three winter seasons a mountain top station at 1620 m above sea level in central Switzerland instrumented with an electrical aerosol analyzer, an optical particle counter, a cascade impactor, meteorological sensors, and snow collectors was operated with high temporal resolution. With the obtained detailed data set size-dependent in-cloud scavenging efficiencies were determined. In-cloud scavenging could be explained as a combination of scavenging could be explained as a commission or nucleation scavenging (for particles with a diameter of 0.2-2 microns) and collection scavenging (by diffusive processes for particles smaller than 0.2 microns, and by impaction processes for those larger than 2 microns). The case-to-case variability of determined efficiencies was very large, being the smaller of simultaneous precipithe result of the influence of simultaneous precipi tation, the solubility of the aerosols, the m concentration of fine particles, and the maximum supersaturation reached during cloud formation. The experimentally determined efficiencies agree, The experimentary determined efficiencies agree, at least qualitatively, with current nucleation theories. Field experiments reported by other authors reconfirm the mean total efficiency of 70% (by aerosol volume) found in this study. The inorganic ion concentrations found in aerosols and precipitation indicate that the precipitation first falling continued outpropositional amounts, of corrections of corrections of the property of corrections of the property tion indicate that the precipitation first falling contained overproportional amounts of coarse, Ca(++)-enriched aerosol particles, advocating that the transformation of cloud water to precipitation water favors droplets with pronounced cloud condensation nuclei characteristics. The submicron particles, consisting mainly of NO3(-), SO4(--), and NH4(+-), are readily incorporated into cloud water, but much less efficiently transformed into

New methods for estimating the bias and resolution of radar and rain gage area were developed which average rainfall measurements over a defined area when both devices are employed simul-taneously. The bias of rain gage measurements for various rainfall amount ranges was estimated from published data, and the bias for radar measurement puoisned data, and the data for radar measurement was then determined through comparison with the rain gage recordings. Resolution estimations were carried out using error variance analysis on corresponding sets of gage and radar observations. The assumptions underlying this technique demand a uniform terrain for rainfall measurements, a large sample of cases, and, for one of the analysis options, a high correlation between radar and gage tions, a nign correlation between radar and gage rainfall measurements. The procedure was illustrat-ed using the gage and rainfall data from the second phase of the Florida Area Cumulus Experiment (FACE-2). The gage sampling error variance esti-mations for various rainfall amount categories using an empirical radar-derived method were examined and compared with those of published studies using alternate methods and were found to studies using atternate methods and were found to be in general agreement. The FACE-2 gage net-work provided more highly resolved rainfall meas-urements than the WSR-57 radar in moderate or heavy rainfall, but the radar exhibited superior resolution in light rainfall if the radar rainfall ad-justment used in FACE was not carried out. The radar rainfall adjustment seemed to reduce radar measurement bias quite effectively, but the resolution was generally not improved and was degraded in below-median rainfall amounts. Mountains often act as barriers to low-level flow creating regions of stagnant, decoupled flow within thermally stratified air masses. This study analyzes how a region of low-level decoupled flow affect the overlying orgraphic cloud. Three different methodologies were used to examine this problem. The first method involved analysis of one and a half months of precipitation and wind data from a 24-station mesonetwork located in the Yampa a 2-station incontension to the rampa River valley and surrounding mountains of north-west Colorado during the winter of 1981/1982 as part of the third Colorado Orographic Seeding Experiment. The second method was a case study analysis of two orographic storms using data from an instrumented cloud physics aircraft to supple-ment the data from the mesonetwork. The third method involved two dimensional numerical simu-lations using Colorado State Univaersity's Region-al Atmospheric Modeling System. The results show that the presence of extensive low-level decoupled flow causes part of the orographic lift of the mountain barrier to be experienced upstream of the barrier. This changes the location of conden-sate production which in turn shifts precipitation upstream and appears to enhance the precipitation efficiency for the entire barrier. (Author's abstract)

PERSISTENT PATTERNS OF THUNDERSTORM ACTIVITY IN THE CENTRAL UNITED STATES,

Indiana Univ. at Bloomington. Dept. of Geogra-

phy.
D. R. Easterling.
Journal of Climate JLCLEL, Vol. 3, No. 12, p
1380-1389, December 1991. 6 fig, 1 tab, 45 ref.

Descriptors: \*Climatology, \*Mathematical models, \*Meteorology, \*Thunderstorms, \*Weather forecasting, \*Weather patterns, Atmospheric circulation, Data interpretation, Mapping, Regional analysis, Seasonal variation.

Observations of thunderstorm events by months for the period 1948-1977 at 106 stations in the central United States were used to examine persistent spatial patterns in thunderstorm occurrence. Maps of the loadings for the first four unrotated Maps of the loadings for the first four unrotated components closely resemble the patterns suggested by Buell as occurring due to the shape of the study area regardless of the variable analyzed. Standard tests (scree, eigenvalue separation) indicated that the first four principal components, which account for 55% of the domain variance, contain non-random patterns that are uncontaminated in the contains the components. ated by sampling errors. An oblique rotation of the first four components to more precisely define the dominant modes of variability in monthly thunder-storm activity for the summer showed strong loadings on the central portion of the country. The second and fourth components showed a moderate out-of-phase relationship between the northern and southern portions of the study area. Cyclonic and frontal activity figure prominently with the areas of above average thunderstorm activity, and anti-cyclonic activity dominates the areas with below average amounts of thunderstorm activity. A map showing regions defined by assigning each grid point to the rotated component on which it loads the highest is presented. The identification of such coherent regions of thunderstorm activity should conerent regions or funderestorm activity snould prove useful in developing 30-90 day forecasts for the summer months. Also, reducing the temporal resolution and including additional data on static stability and lower-and upper-level flow patterns would help refine these patterns, for useful short-term thunderstorm forecasting. SPRING AND SUMMER 1988 DROUGHT OVER THE CONTIGUOUS UNITED STATES-CAUSES AND PREDICTION.

Scripps Institution of Oceanography, La Jolla, CA.

ate Research Group. J. Namias

J. Namias.

J. Namias.

Journal of Climate JLCLEL, Vol. 4, No. 1, p 54-65, January 1991. 13 fig, 3 tab, 14 ref. NSF Grant ATM 84-07891, USGS Grant 14-08-0001-G1483, and National Climate Program Office Grant NA81AA-D-0054.

Descriptors: \*Climatology, \*Drought, \*Meteorology, \*Precipitation, \*Seasonal variation, \*Weather forecasting, Atmospheric circulation, Climatic data, Model studies, Temperature, Water deficit.

The 1988 summer drought over much of the contiguous United States and its generation from conditions during the preceding spring was analyzed in terms of hemispheric flow patterns in the midtroposphere, temperature and precipitation anomalies, and sea surface temperature anomalies. Conditions in March were especially indicative of the ensuing drought, since a model routinely employed in long-range forecasting showed that the March circulation would most likely be followed by a hot dry April, May, and June over much of the nation—a pattern which persisted into early summer. This result suggests that the initiation of the drought was rooted in extratropical climate variations, an alternative hypothesis to one which attributes the persistent drought-producing circulation to oceanic and atmospheric conditions in the tropics. In many respects the summer drought of 1988 was similar to earlier great droughts of the Great Plains, although it was spatially more extensive. Attempts by three forecast groups to predict the summer conditions from spring's were moderately successful, though none of these anticipated the drought's severity and extent. The underlying reasons for the summer forecast made by the author were verified using objective tools. Premonitory signs showed up in antecedent seasons when deficient precipitation occurred, when climawhen deficient precipitation occurred, when clima-tological contingencies provided alerts, and when extratropical sea surface temperature patterns evolved in a conductive manner. A new modified barotropic model iterating from the May midtro-pospheric height pattern using a mean summer estimate of seasonal forcing produces a reasonably successful estimate of the summer circulation and, in retrospect, even more so when initialized from the March height pattern for the April, May, and June period of inception. SPATIAL DISTRIBUTION OF PRECIPITA TION SEASONALITY IN THE UNITE STATES,

Environmental Protection Agency, Research Tri-angle Park, NC. Atmospheric Research and Expo-sure Assessment Lab.

Journal of Climate JLCLEL, Vol. 4, No. 4, p 373-385, April 1991. 12 fig, 2 tab, 33 ref.

Descriptors: \*Climatology, \*Mapping, \*Precipita-tion, \*Regional analysis, \*Seasonal variation, \*Spa-tial distribution, Carbon dioxide, Climatic data, Climatological models, Global warming, Mathe-matical models, Model studies, Temperature.

A very good quality database using spatial aggregated data has allowed the development of a detailed portrait of precipitation seasonality over the United States. Variation of seasonality, decade by decade, has shown that the seasonal precipitation patterns in some areas are very fixed, while others change considerably. This more detailed understanding of the nature of this important climate stanting of the nature of ints important climate variable should assist in the development of better process relationships between climate and regional ecology. A preliminary analysis of the relationship of seasonality to variations in rainfall amount or of sessonality to variations in rainfall amount or annual temperature, do not show any obvious connection in the record. However, global climate models (GCMs) do seem to be able to match certain important aspects of precipitation seasonality over the United States. This would lead one to expect that more careful and quantitative studies of the relationship of seasonality to other climate variables could be done using the GCMs. Scenarios of climates that have been changed by the presence of twice the CO2 found in today's atmosphere produced by several models do suggest that precipitation seasonality could significantly change precipitation seasonality could significantly change in certain parts of the country. Such changes, were they to happen, would have profound effects on natural ecology, agriculture, and water resources; to name but a few areas of critical importance. Since increases in CO2 and other radiatively important trace gases are very real, and contin

#### Precipitation—Group 2B

this result suggests that clear importance of developing a better understanding of how the climate may change, and what the consequences of that change may be. (Medina-PTT) W91-11414

#### FOUR-PARAMETER MODEL FOR THE ESTI-MATION OF RAINFALL FREQUENCY IN SOUTH-WEST ENGLAND,

C. Clark.

Meteorological Magazine MTMGA5, Vol. 120, No. 1423, p 21-31, February 1991. 11 fig, 7 tab, 24

Descriptors: \*England, \*Mathematical models, \*Meteorology, \*Model studies, \*Rain gages, \*Rainfall distribution, \*Rainfall intensity, \*Rainfall rate, \*Weather patterns, Analytical methods, Culverts, Design storms, Flood control, Spillways.

The two best known methods used to estimate the return period (the number of years within which a particular extreme value is likely to be exceeded particular extreme value is likely to be exceeded only once) of rainstorms, namely the Bilham method and that used in Volume II of the Flood Studies Report (FSR-II) produce different results. In general the FSR method gives the higher return periods. This difference is of great practical importance for the design of culverts, flood alleviation schemes, and reservoir spillways. FSR-II grew out of the acknowledged inadequacies of the now largely extinct Bilham method. However, an earlier work by Rootman and Willis showed that for largely extinct blinam method. However, an earni-er work by Bootman and Willis showed that for parts of Somerset, the FSR-II method gave an under-estimation of the magnitude of 2-day rain-fall. This study presents rainfall frequency analysis over the Somerset Division of the Wessex Water over the Somerset Division of the Wessex Water Authority and the South West Water Authority areas in England using a new method for estimating the frequency of heavy rainfall by comparing the number of sites whose return periods are in excess of the 5% probability level of exceedance. It suggests that the large number of rare events as It suggests that the large number of rare events as given by the FSR-II is too high and that the associated FORGE method by Stewart also gives results which suggest that the problem of dependence between widely spaced rain-gages has not yet been overcome. The area was chosen partly because it included the area studied by Bootman and Willis who only considered 2-day rainfall, and also because southwest England is norm to beave; and because southwest England is prone to heavy rainfall. A total of 44 autographic rain-gage records. A comparison of the calculated and observed return periods of storm events showed that the model was capable of giving realistic results and with an accuracy good enough to be used for design purposes. This new method overcomes the problem of intra-Inis new method overcomes the problem of intra-regional variation of growth factors by assigning a growth factor specific for the site in question in contrast to the uniform national growth-curve for the FSR-II and regional curves for the FORGE method. Descriptors: \*Athens, \*Environmental gradient, \*Greece, \*Hypsometric analysis, \*Meteorological data, \*Meteorology, \*Precipitation mapping, \*Rainfall distribution, \*Seasonal variation, \*Weather patterns, Rain gages, Thunderstorms, Topography.

The knowledge of the spatial distribution of rainfall in the Greater Athens Area (GAA) in Greece is limited although rainfall measurements have been carried out in the city of Athens for well over 130 years. The annual and seasonal spatial distribution of rainfall in the GAA was studied from 1985tion of rainfall in the GAA was studied from 1985-1989 using rainfall data from 24 rain-gauges. These rainfall distributions and the temporal variations of rainfall during the 5-year period revealed strong discrepancies among the different parts of the ob-served area. Although the rainfall in the GAA generally presented a seasonal variation with a

maximum during the cold period and a minimum during the warm period of the year, a secondary minimum was observed during winter which intensified with higher rainfall amounts measured in March. The annual rainfall amounts increased with March. The annual rainfail amounts increased with altitude in the GAA by 68.5 mm for each 100 m increase of the station height above sea level. The correlation coefficient between the monthly mean rainfall and the station height showed a seasonal variation with high values during the cold period and low values during the warm period. The annual spatial distribution of rainfall presented a gradient between inland and coastal areas. Consequently, rainfall at Marathon Area doubled as compared with the coastal areas. The same districompared win the coastal areas. In e same distri-bution pattern was observed for January and Octo-ber, while for April and July, the gradient was much less pronounced due to thunderstorm activi-ty, which is less influenced by the local topography. Descriptors: \*Alabama, \*Clouds, \*Meteorology, \*Storms, \*Thermodynamics, \*Thunderstorms, \*Weather patterns, Air masses, Meteorological data, Precipitation, Radar.

On 20 July 1986, a weakly sheared thunderstorm formed over northern Alabama during the Micro-burst and Severe Thunderstorm project. The storm produced a strong, damaging microburst and is believed to be the first well-documented case from a warm-based cloud with a shallow subcould laver. a warm-based cloud with a shallow subcould layer. So far, only numerical simulations of microbursts from these cloud types have been analyzed. During its life cycle a comprehensive dataset was collected with the use of Doppler radar and cloud photography. A kinematic, dynamic, and thermodynamic analysis of this airmass thunderstorm was rade. Most peech live who feet that the domination of the control of the made. Most notable was the fact that the dominant cell in this storm closely resembled the Byers and Braham model for warm-based, airmass storms. Several phenomena never documented for this storm-type was observed. One of these was a strong and deep downdraft recorded at midlevels with an associated weak echo trench. Its origin appeared to be related to a weak entrainment proc-ess. A midlevel inflow which caused a visible constriction in the storm cloud was also observed. This inflow resulted in a division of the thermal This inflow resulted in a division of the thermal buoyancy into two maxima in the vertical: one associated with the precipitation core and the other with strong positive vertical motions in the growing cumulus turret. In addition, a downdraft separate from that seen at midlevels developed at low levels and caused a microburst outflow at the surface. This downdraft appeared to be initiated by precipitation loading and intensified by negative thermal buoyancy. The Byers and Braham model of the cumulus, mature and dissipating stages, was analyzed in light of these new features. (Medina-PTT) PTT W91-11417

## NUMERICAL SIMULATIONS OF THE EVO-LUTION OF A COLD FRONT AND ITS PRE-CIPITATION.

Illinois Univ., Urbana. Lab. for Atmospheric Re-

search.
H. M. H. Juang.
Monthly Weather Review MWREAB, Vol. 119,
No. 2, p 385-411, February 1991. 23 fig. 1 tab, 25
ref. NSF Grants ATM84-15222 and ATM8700778.

Descriptors: \*Meteorology, \*Model studies, \*Precipitation intensity, \*Precipitation mapping, \*Tem-perature gradient, \*Weather patterns, Convective precipitation, Mathematical models, Meteorologi-cal data, Moisture density.

Short-range (36-h) simulations of a surface cold front that occurred over the Great Plains of the Iront that occurred over the Great Plans or the United States during the Severe Environmental Storm and Mesoscale Experiment-Atmospheric Variability Experiment period were made using a significantly modified version of a hydrostatic, sigma-coordinate, quasi-Lagrangian, primitive-equation gridpoint model. The evolution of the environment associated with the cold front was well predicted by the model when compared with went predicted by the model when configured was analyses and observations of the cold front location, horizontal temperature gradient, wind field dry line, temperature inversion, and precipitation. The current model results caught several observed features that were not present in the other mesos-cale model results. The evolution of several local maxima of frontal intensity, defined in terms of temperature gradient, were related to the combination of local maxima of convergence and deformation effects in different locations along the cold tion effects in different locations along the cold front. The genesis of negative relative vorticity along the inverted cold front over the lee of the United States Rockies was related to the effect of solenoidal forcing. The model precipitation agreed well with observation in terms of timing and loca-tion. The evolution of maximum precipitation fol-lowed the evolution of the maximum low-level convergence ahead of the cold front, where ample convergence areas of the controls, where amperiors moisture combined with potential instability. The generation of the temperature inversion in the vicinity of the frontal surface over the southern portion of the cold front prohibited convection there, and localized the frontal precipitation along the northern portion of cold front and east of southern temperature inversion. The temperature inversion was generated by differential temperature advection through the frontal circulation within the PBL, and modified by the vertical stretching effect that stabilized the lower layer behind the cold front and destabilized ahead of the cold front. #### SATELLITE-DERIVED INTEGRATED WATER-VAPOR DISTRIBUTION IN OCEANIC MIDLA-TITUDE STORMS: VARIATION WITH REGION AND SEASON.

Washington Univ., Seattle, Dept. of Atmospheric

L. A. McMurdie, and K. B. Katsaros. Monthly Weather Review MWREAB, Vol. 119, No. 3, p 589-605, March 1991. 12 fig, 3 tab, 41 ref. NASA Contract NAS8-36473 and NASA Grant

Descriptors: \*Climatology, \*Cyclonic precipita-tion, \*Meteorology, \*Remote sensing, \*Satellite technology, \*Seasonal variation, \*Storms, \*Water vapor, \*Weather patterns, Air temperature, Latitudinal studies, Precipitation mapping, Radiometry, Radiosondes, Regional analysis, Water temperature. Weather.

With the atmospheric water-vapor content infor-mation available from the SEASAT and Nimbus-7 mation available from the SEASAL and Nimous-Scanning Multichannel Microwave Radiometers (SMMR), differences in water-vapor distribution between cyclonic storms in different regions of the global ocean can be examined in more detail than previously possible from radiosondes. SMMR-derived integrated water vapor is a robust and de-pendable variable of the same accuracy as integrated radiosonde soundings. In this study, maximum and minimum water-vapor content in the vicinity of cold fronts of 80 storms that occurred in the North Atlantic, North Pacific and Southern oce are compared. North Atlantic storms had signifi-cantly higher maximum and minimum water-vapor content near cold fronts on average than North Pacific or Southern ocean storms for both the warm and cold seasons. These differences are attributed to warmer sea surface temperatures and air temperatures in the North Atlantic, and higher baroclinity and consequently stronger upward motion in North Atlantic storms. Additionally, some of the differences may be attributed to the fact that the North Atlantic storms generally occur at lower latitudes than the storms in the other regions. Furthermore, the North Atlantic storms had significantly higher maximum and minimum water-vapor content near cold fronts on average

#### **Group 2B—Precipitation**

than the Southern Ocean storms for both the warm and cold seasons. These differences are attributable to warmer sea surface temperatures in the North Pacific during the warm season, and to less mois-ture transport by Southern Ocean storms com-pared to North Pacific storms during the cold season. Two examples of water-vapor content in a South Atlantic storm are given to contrast with the Southern Ocean cases. The South Atlantic storm had much higher maximum water-vapor content near the cold front than most Southern Ocean storms. (Author's abstract) W91-11419

SQUALL LINE IN SOUTHERN GERMANY: KINEMATICS AND PRECIPITATION FORMA-TION AS DEDUCED BY ADVANCED POLARI-METRIC AND DOPPLER RADAR MEASURE-MENTS.

Deutsche Forschungsanstalt fuer Luft- und Raum-fahrt e.V., Oberpfaffenhofen (Germany, F.R.). Inst. fuer Physik der Atmosphare. P. F. Meischner, V. N. Bringi, D. Heimann, and H.

Monthly Weather Review MWREAB, Vol. 119, No. 3, p 678-701, March 1991. 22 fig, 1 tab, 47 ref. NSF Grant ATM-8703126 and ATM-8915141.

Descriptors: \*Germany, \*Meteorological data collection, \*Meteorology, \*Precipitation intensity, \*Precipitation mapping, \*Radar, \*Squalls, \*Thunderstorms, \*Weather patterns, Clouds, Hail, Polarization, Rain, Reflectance.

Squall lines are highly organized, long lasting, mesoscale thunderstorm complexes. The main mesoscale thunderstorm complexes. The main characteristic is a line of deep convective cells some 100 km in length forming the leading edge of the system. A multiscale analysis of a squall line system showed that the squall line was initiated as part of a synoptic-scale frontal zone. The main emphasis then is on the polarimetric and Doppler radar measurements which give insight into the mesoscale and microscale structure of the kinematmesoscale and microscale structure of the kineman-ics and the precipitation microphysics especially within the new cells growing ahead of the squall line, and within the main precipitation system. The principal polarimetric measurements considered are the differential reflectivity (Z-DR) and a relat-ed newly derived parameter termed the difference reflectivity or Z-DP which is useful in detection of rain-ice mixed phase precipitation. A limited amount of time series data was analyzed to derive amount of time series data was analyzed to derive the specific differential phase (k-DP) and the backscatter differential phase between horizontal and vertical polarizations. A brief overview of the microphysical interpretation of these parameters is provided. The newly grown clouds were identified as positive Z-DR columns, i.e., regions of low reflectivity and unusually large Z-DR. Within the high reflectivity of the squall line, intense precipi-tation in the form of randforms mixed with smited tation in the form of raindrops mixed with small, melting hail may be inferred. The radar observations were shown to be in good agreement with a hail melting model. A conceptual model of the squall line is provided based on the Doppler and polarimetric data. It demonstrates the internal circulation structure as well as the contribution of melting ice particles to the cold pool dynamics.

SENSITIVITY STUDIES OF TROPICAL STORM GENESIS USING A NUMERICAL

National Oceanic and Atmospheric Administra-tion, Princeton, NJ. Geophysical Fluid Dynamics

Monthly Weather Review MWREAB, Vol. 119, No. 3, p 721-733, March 1991. 9 fig, 28 ref.

Descriptors: "Hurricanes, "Meteorology, "Model studies, "Precipitation mapping, "Storms, "Tropical cyclones, "Weather patterns, Climatology, Evaporation, Numerical analysis, Relative humidity, Synoptic analysis, Temperature, Wind pressure.

A case of developing (Hurricane David) and a case of non-developing disturbance ( did not develop past the depression stage) that occurred a week

apart in the tropical Atlantic in the FGGE year (1979) was analyzed thoroughly with numerical simulations. At one point in their evolution the disturbances had quite similar values of low-level vorticity. In the developing case of Hurricane David, the disturbance propagated along in a lowlevel wave trough with an accompanying high wind maximum. In the non-developing case the initial disturbance was also embedded in a wave initial distributions was also embedded in a wave trough with an associated wind maximum. This low-level wave propagated westward leaving the depression in its wake. The different environmental flow was responsible for the different behavior. Synoptic and budget analyses revealed significant differences in disturbance structure and velocity and equivalent potential temperature tendencies at and equivalent potential temperature reindences at the time of approximate equal strength of the two disturbances. The evolution of these two disturb-ances was quite robust even to reasonable increases to the initial relative humidity. Supplementary experiments of the developing case were performed by altering the sea surface temperature and surface evaporation. The difference in storm evolution was minor in a case when climatological mean values of sea surface temperatures were specified. The climatological mean values were approximately 0.5 K lower than the August 1979 mean used in the control simulation. In addition, an experiment without evaporation led to a propagating easterly without evaporation led to a propagating easterly wave with little development. Furthermore, when the evaporation was specified to a climatological constant value, there was intensification into a weak tropical storm with a rather peculiar structure. Apparently, at least in this case, processes other than evaporation-wind feedback led to moderate storm intensification. (Author's abstract)

CONVECTIVE CELL IN A HURRICANE RAIN-

National Center for Atmospheric Research, Boulder, CO.

Descriptors: \*Convective precipitation, \*Hurricanes, \*Meteorological data collection, \*Meteorology, \*Precipitation, \*Radar, \*Storms, \*Tropical cyclones, Clouds, Cyclones, Ice, Rainband, Wind.

On 10 October 1983 the two National Oceanic and On 10 October 1983 the two National Oceanic and Atmospheric Administration WP-3D aircraft com-pleted a mission designed to provide airborne Doppler radar data for a convective cell embedded in a weak rainband on the trailing side of Hurri-cane Raymond. Comparisons of the wind field produced from the pseudo-dual-Doppler radar technique with in-situ wind measurements suggest tecnnique with in-stil wind measurements suggest that the larger convective-scale features may be resolved if the sampling time is kept to a minimum. The convective cell moved downband faster than any environmental winds but slightly slower than the winds found in the reflectivity core that delin-eates the cell. In the core of the cell the tangential wind was increased and the radial inflow turned to outflow with respect to the circulation center. The flow field demonstrated that the downband strati-form portion of a rainband is not from cells currently active since the updraft detrains upwind relative to the cell but rather it is due to the fallout from ice particles placed into the upper tropo-sphere by clouds that have since dissipated. The mass flux of this cell was estimated to be 5%-10% of the mass flux accomplished by an eyewall of a moderate tropical cyclone. This finding supports the concept that large, convectively active rain-bands have a major effect on the subcloud layer air flowing toward the eyewall. (Author's abstract) W91-11422

ASSESSMENT OF VAS-DERIVED RETRIEV-ALS AND PARAMETERS USED IN THUNDER-STORM FORECASTING.

Florida State Univ., Tallahassee. Dept. of Meteor-

ology. H. E. Fuelberg, and S. R. Olson. Monthly Weather Review MWREAB, Vol. 119,

No. 3, p 795-814, March 1991. 13 fig, 3 tab, 34 ref. NASA Grant NAG8-653.

Descriptors: \*Infrared imagery, \*Meteorological data collection, \*Meteorology, \*Precipitation mapping, \*Radiosondes, \*Remote sensing, \*Satellite technology, \*Thunderstorms, \*Weather forecasting, Dewpoint, Humidity, Temperature.

Geostationary meteorological satellites launched by the United States since September 1980 have contained the Visible Infrared Spin Scan Radiome-ter Atmospheric Sounder (VAS). With seven temperature, three water vapor, and two window channels, VAS provides infrared radiances from channels, VAS provides infrared radiances from which vertical profiles of temperature and humidity can be derived. Operational VAS satellite retrievals and derived parameters used in forecasting severe local storms were evaluated against corresponding radiosonde (RAOB) values. VAS products also were compared with the first, suggest input sponding radiosonde (RAOB) values. VAS products also were compared with the first-guess input to the retrieval algorithm. The evaluation methodology was to pair each radiosonde observation (RAOB) with the closest VAS retrieval within 50 km during a 4-month period in 1986. VAS temperatures agreed closely with radiosonde values; however, VAS dewpoints showed somewhat less agreement. VAS/RAOB sounding differences were poorly correlated with the number of pixels from which the retrievals were prepared. A disappointing finding is that the retrievals degraded the first guess about as often as they improved it. Horizontal gradients of VAS products generally were stronger than those from radiosonde. VAS precipitable water agreed better with the ground precipitable water agreed better with the ground truth than did dewpoints at individual levels, but VAS thicknesses were not much improved over the already accurate VAS temperatures. Results for the severe storms forecasting parameters indicated that VAS/RAOB discrepancies increased with the amount of manipulation required during computation. Of all the parameters examined, VAS-derived lifted index exhibited the best agreement with RAOB versions. VAS retrievals provided poor measures of the low-level negative buoyant energy that must be overcome before convecant energy that must be overcome before convec-tion can begin. Agreements between VAS/RAOB versions of the K index, Showalter index, and several other parameters were intermediate to those of positive buoyant energy and lifted index. (Medina-PTT) W91-11423

DYNAMICAL FORCING AND MESOSCALE ORGANIZATION OF PRECIPITATION ORGANIZATION OF PRECIPITATION BANDS IN A MIDWEST WINTER CYCLONIC

Illinois Univ. at Urbana-Champaign. Dept. of Atmospheric Scien

M. T. Shields, R. M. Rauber, and M. H.

Monthly Weather Review MWREAB, Vol. 119, No. 4, p 936-964, April 1991. 19 fig, 2 tab, 36 ref. NSF Grant ATM-8816309.

Descriptors: \*Cyclonic precipitation, \*Illinois, \*Meteorology, \*Precipitation, \*Precipitation mapping, \*Storms, Meteorological data, Radar.

A winter storm that developed over and moved through the midwestern United States on February 10-11, 1988 produced several inches of snowfall locally over east-central Illinois. Analysis of the mesoscale organization of the storm revealed the mesoscale organization of the storm revealed the presence of complex banded structure throughout its 17-h evolution. Three distinct types of mesos-cale precipitation bands were identified during the course of the storm using a 10-cm Doppler radar as part of the University of Illinois Winter Precipita-tion Program. The bands had different orientations, directions of movement, relationships to synoptic-scale frontal zones, and mechanisms of development. The first band type occurred early in the storm along zones of confluence in the surface flow associated with a dissipating frontal boundaflow associated with a dissipating frontal boundary. Convergence along the primary confluence axis produced an extremely narrow but intense mesoscale precipitation band that existed for over 5 h. A second smaller band also was present parallel to the first that was shorter lived. The second type of band developed several hours after the dissipation

#### Snow, Ice, and Frost-Group 2C

of the narrow bands along an inverted pressure trough that separated cool polar and cold arctic air trough that separated cool polar and cold arctic air masses. Strong boundary-layer convergence within an area of frontogenetical forcing along the trough resulted in a region of forced low-level convection that produced the band. The final group of mesoscale precipitation bands was a series of irregularly spaced bands that formed over a surface cold front undergoing frontogenesis. The atmosphere in the region of the bands was characterized by near-neutral conditional symmetric stability. This single case study clearly demonstrated the complex nature of the mesoscale organization of continental cyclonic storms. (Medina-PTT)

VAPOR DIFFUSIONAL GROWTH OF FREE-FALLING SNOW CRYSTALS BETWEEN -3 AND -23 C.

Hokkaido Univ., Sapporo (Japan). Inst. of Low Temperature Science.
B. Takahashi, T. Endoh, G. Wakahama, and N.

Journal of the Meteorological Society of Japan JMSJAU, Vol. 69, No. 1, p 15-30, January 1991. 20 fig, 7 tab, 27 ref.

Descriptors: \*Crystal growth, \*Snow, \*Snowfall, \*Vapor diffusion, Diffusion, Precipitation, Snow crystals, Temperature effects.

The characteristics of snow crystal growth by vapor diffusion at water saturation and in free fall were quantitatively investigated in a vertical supercooled cloud tunnel for periods up to 30 minutes at temperatures from -3 to -23 C. The results showed that the basic growth habits were plates (> 4.0 C), columns (-4.0 to -8.1 C), plates (-8.1 to -22.4 C) and columns (<-22.4 C), respectively. At about -5.5, -12, -14.5, -16.5, and -18 C, crystal shapes were enhanced with time. For an isometric crystal, the slope of a log-log plot between the crystal mass and the growth time showed the Maxwellian value of 1.5. The mass growth rate of a shape-enhanced crystal was larger than that of the isometric crystal, indicating more effective vapor transfer on the shape-enhanced crystal. In the case of shape-enhanced planar crystals grown at around -12, -14.5 and -16.5 C, ventilation effects became recognizable, whereas the effect was not evident for needle

crystals grown at about -5.5 C. This suggests that the characteristic length of the flow field even around a needle crystal is along the a-xis. The ventilation effect became significant when the Reynolds number exceeded about 2 (sector) and 5 (dendrite). Linear relationships between the drag coefficient and the Reynolds number were found in log-log plots. (Author's abstract) W91-10515

OBSERVATION OF THE LIQUID WATER CONTENT OF MELTING SNOWFLAKES WITH A NEW INSTRUMENT.

Y. Sasyo, T. Mori, O. Onazaki, and T. Saito. Journal of the Meteorological Society of Japan JMSJAU, Vol. 69, No. 1, p 83-90, January 1991. 4 fig. 1 tab, 6 ref.

Descriptors: \*Measuring instruments, \*Melting, \*Snow, \*Snowflakes, Computer models, Fall velocity, Precipitation, Water content.

In order to measure the liquid water content of a melting snowflake, a new automatic instrument based on a filter paper technique has been devel-oped and used for field observation of sleet. Analyoped and used or held observation of sieet. Analysis of the observational data indicated that the relationship between the liquid water content W and the mass of the snowflake m (mg) could be expressed as W = beta times mass to the negative alpha, where alpha determines the slope of the line alpha, where alpha determines the slope of the line and beta equals the liquid water content of a snow-flake with a mass 1 mg. Alpha ranges from 0.27 to 0.95 (0.53 in an average) and beta ranges from 0.07 to 0.51 (0.25 in an average). A simple model for the melting of snowflakes showed that alpha was a parameter depending on the fall velocity of the snowflake alone and parameter beta depends on the quantity of heat transferred from ambient air to the snowflake and the density of the ice skeleton in the snowflake and the density of the ice skeleton in the melting snowflake as well as the fall velocity. GEOCHEMICAL EVIDENCE SUPPORTING T. C. CHAMBERLIN'S THEORY OF GLACIA-

Melbourne Univ., Parkville (Australia). Dept. of

Geology, M. E. Raymo. Geology GLGYBA, Vol. 19, No. 4, p 344-347, April 1991. 1 fig. 54 ref. National Science Foundation Grant No. OCE88-10949.

Descriptors: \*Climatic changes, \*Geochemistry, \*Glaciation, Carbon dioxide, Chemical interactions, Chemical reactions, Climates, Erosion, Orogeny, Strontium radioisotopes, Tectonics,

In 1899, T. C. Chamberlin proposed that the CO2 content of the atmosphere decreased during times of enhanced continental erosion, ultimately resulting in glacial epochs. He ascribed the incre ing in glacial epochs. He ascribed the increase in the rate of chemical weathering (relative to the rate of supply of CO2 from the earth's interior) to increased orogenic activity and globally higher average elevations, which promoted rapid chemi-cal erosion of silicates. The oceanic record of strontium isotopes, preserved in marine sediment, supports his suggestion that glacial climates during the Phanerozoic are in part linked to increases in the rate of global chemical erosion relative to outgassing from the earth's interior. Further, the close correspondence of the major tectonic episodes of the Late Ordovician and Early Silurian, the Devonian, the Carboniferous and the late Ce-nozoic to times of increased continental erosion nozone to times of increased continental evolutions and glaciation suggests that Chamberlin's hypothesis of the cause of glacial periods should be revived. EFFECTS OF CLIMATE CHANGE ON DIS-CHARGES AND SNOW COVER IN FINLAND, National Board of Waters, Helsinki (Finland). Water Research Inst.

B. Vehvilainen, and J. Lohvansu Hydrological Sciences Journal HSJODN, Vol. 36, No. 2, p 109-121, April 1991. 7 fig, 10 tab, 6 ref.

Descriptors: \*Climatic changes, \*Finland, \*Global warming, \*Greenhouse effect, \*Model studies, \*Snow cover, Carbon dioxide, Evaporation, Flow discharge, Precipitation, Rainfall-runoff relation-

The effects of climate change obtained through model simulations on runoff and snow cover in Finland have been investigated. The results were based on hydrological model simulations using the information from one climatic general circulation model (GISS) scenario with doubled atmospheric moute (GISS) section with toubled atmospheric carbon dioxide as input. According to the GISS model scenario, the temperature increase in Fin-land will be 2-6 C, the precipitation increase 10-30 mm per month and the evaporation increase 5-30 mm per month. The effects of these climatic changes on runoff and snow cover have been evaluated in twelve different watersheds by hydrological watershed models. According to the results the mean discharge (MQ) increases by 20-50%, the mean minimum discharges (MNQ) increase considerably in winter due to two to three months shorter snow cover period and the mean maximum discharges (MHQ) decrease due to diminished maximum snow water equivalents. In southern Finland persistent winter snow cover will vanish. (Author's abstract)

VARIATION OF THE STABLE ISOTOPES OF WATER WITH ALTITUDE IN THE SAINT ELIAS MOUNTAINS OF CANADA.

National Hydrology Research Inst., Saskatoon (Saskatchewa

(Saskachewan). G. Holdsworth, S. Fogarasi, and H. R. Krouse. Journal of Geophysical Research (D) Atmospheres JGRDE3, Vol. 96, No. 4, p 7483-7494, April 20, 1991. 13 fig, 54 ref.

Descriptors: \*Altitude, \*Canada, \*Climatology, \*Paleoclimatology, \*Snowmelt, \*Stable isotopes, Atmospheric water, Oxygen isotopes, Snow, St Elias Mountains, Troposphere, Yukon.

Stable isotopes of water, measured in melt samples taken from snow pits and cores at locations be-tween 1750-m and 5930-m altitude on Mount Logan (5951 m) and between 2900 and 4900 m on Logan (5951 m) and between 2900 and 4900 m on Mount Steele (5079 m), in the Saint Elias Mountains, Yukon (Canada), show a distinctive altitudinal distribution. Several delta-18-O and delta-versus altitude profiles indicate the general persistence of a nearly iso-delta step, or staircase structure separating a lower region of altitude-dependent isotopic fractionation between 1750 and 3350 m from another apparent fractionation sequence ap-

#### Group 2C—Snow, Ice, and Frost

pearing above about 5300 m. Both sequences, especially the lower one, indicate orderly processes. On the one hand, postdepositional changes to isotope ratios in snow at different altitudes may cause distortions to an otherwise nearly monotonic iso-tope fractionation sequence, but the main anomaly tope fractionation sequence, but the main anomaly appears to be far too large to be explained in this way. On the other hand, an explanation linked to processes occurring in the lower and midtroposphere is based on established meteorological principles as well as on upper air data. This hypothesis is proposed as the primary one to explain the gross features of the observed isotope profiles. It is committed to the contract of t patible with the concept of secondary-source mois-ture arriving via the upper troposphere, and it does not exclude the effects of postdepositional strati-graphic and stable isotope ratio changes. Over graphic and stable isotope ratio changes. Over interannual time scales, any vertical modulation of the observed isotope-altitude structure, from, for example, changes in wind regime, would give rise to an additional signal in any ice core delta time series. These findings identify a potential difficulty in the interpretation of stable isotope records obtained from high mountain ice core sites. It is possible that the results may have application to atmospheric circulation modeling, where the ef-fects of extreme topography are being studied. (Author's abstract) W91-11220

Previous discussions of the catastrophic drainage of ice-dammed lakes have centered on mechanisms where characteristics of the lake are crucial to drainage initiation, i.e., dam flotation or tunnel formation at a critical lake depth. A different mechanism for lake drainage has been proposed where drainage initiation depends on the charac-teristics of the glacier and is independent of the characteristics of the lake. Prediction of this mechanism must be based on glacier dynamics, whereas the mechanisms most commonly discussed previ-ously are best predicted primarily on the basis of lake evolution. An ice-dammed lake at the margin of the glacier Solheimajokull, in southern Iceland, of the glacier Solheimajokull, in southern Iceland, was observed to drain rapidly into the subglacial or englacial drainage system, supplying water and debris to the bed or interior of the glacier. Geomorphological evidence suggests that the lake drains and refills periodically, discharging up to 13,300 cu m of water into the glacier-hydrological system. The depth of the maximum lake is insufficient to cause either floation of the ice mercinet. ient to cause either flotation of the ice margin or tunnel opening by plastic deformation of the ice. It is suggested that sudden drainage is related to ice-bed separations associated with specific glacier flow states rather than to a critical lake depth threshold. This mechanism of lake drainage has implications for conditions at the glacier bed, for the development of basal ice and for the entrainment of debris into the glacier, as well as for the prediction of potentially hazardous catastrophic drainage events and jokulhlaups from ice-dammed lakes. VARIABILITY OF GLACIER MASS BAL-ANCES IN WESTERN NORTH AMERICA. ANCES IN WESTERN NORTH AMERICA. Geological Survey, Tacoma, WA. R. A. Walters, and M. F. Meier. Geophysical Monograph GPMGAD, No. 55, 1989, p 345-374, 9 fig, 4 tab, 37 ref.

Descriptors: \*Climatology, \*Glaciers, \*Mass bal-ance, \*North America, Alaska, Atmospheric circu-lation, British Columbia, El Nino/Southern Oscil-lation, Hydrologic budget, Meteorology, Precipita-tion, Temperature, Washington.

The mass balance of glaciers depends on precipita-tion and temperature in winter and on temperature and insolation in summer. For glaciers in western orth America these meteorological variables are influenced by the large-scale atmospheric circula-tion over the North Pacific Ocean. This study addresses the relation between mass balance at six glaciers in western North America and large-scale atmospheric effects at interannual time scales, and longer-term cumulative changes in glacier volume.

Mass balance data for these glaciers spans 20 years (1966-1985). Similarities and differences between the mass balances are brought out by using empirithe mass balances are brought out by using empirical orthogonal function analysis. Almost 80% of the variance is contained in the first 2 empirical modes (61%, 177%). The first mode shows a negative correlation between the balances for the Alaska glaciers and for the other glaciers. This relation is due to the steering effect of the Aleutian/Gulf of Alaska Low; when it is dry in Washtuni/Guir of Alaska Low; when it is dry in wasnington it is usually wet in Alaska and vice versa. The first mode also shows that dry conditions in Washington and wet conditions in Alaska are associated with a positive Pacific North America (PNA) index and usually with El Nino/Southern Oscillation (ENSO) events. In addition, there was a several-year bias introduced after the 1977 ENSO event that the mass balances in Washington were more negative, and those in Alaska were more positive than before. Over decade time scales the cumulative more before. the cumulative mass balances show an inverse relaune cumuatuve mass balances show an inverse rela-tion between balance at the coastal Alaska glacier and at the southern glaciers. However, the overall trends display a different relation with negative trends at all glaciers except two in the coastal region of British Columbia and Alaska. (Author's abstract) abstract) W91-11391

SNOW AND ICE PERTURBATION DURING HISTORICAL VOLCANIC ERUPTIONS AND THE FORMATION OF LAHARS AND

THE FORMATION OF LATIONS AND ASSESSED A

Descriptors: \*Floods, \*Ice, \*Lahars, \*Mudflows, \*Snow, \*Volcanoes, History, Lava, Melting, Pyroclastic events, Snowmelt, Snowpack.

Historical eruptions have produced lahars and Historical eruptions have produced lahars and floods by perturbing snow and ice at more than 40 volcances worldwide. Most of these volcances are located at latitudes higher than 35 degrees; those at lower latitudes reach altitudes generally above 4000 m. Volcanic events can perturb mantles of snow and ice in at least five ways: (1) scouring and snow and ice in at least five ways: (1) scouring and melting by flowing pyroclastic debris or blasts of hot gases and pyroclastic debris; (2) surficial melting by lava flows; (3) basal melting of glacial ice or snow by subglacial eruptions or geothermal activity; (4) ejection of water by eruptions through a crater lake; and (5) deposition of tephra fall. Historical records of volcanic eruptions at snow-clad volcanoes show the following: (1) flowing pyroclastic debris (pyroclastic flows and surges) blasts of hot gases and pyroclastic debris are the most common volcanic events that generate lahars and floods; (2) surficial lava flows generally cannot melt snow and ice rapidly enough to form large lahars or floods; (3) heating the base of a glacier or anatyracit busined being the control of the c snowpack by subglacial eruptions or by geother-

mal activity can induce basal melting that may result in ponding of water and lead to sudden outpourings of water or sediment-rich debris flows; (4) tephra falls usually alter ablation rates of snow and ice but generally produce little meltwater that results in the formation of lahars and floods; (5) lahars and floods generated by flowing pyroclastic debris, blasts of hot gases and nowing pyroclastic debris, or basal melting of snow and ice commonly have volumes that exceed 100,000 cu m. The glowing lava (pyroclastic flow) which flowed with force over ravines and ridges, gathered in the basin quickly and then forced downward. As a result, tremendously wide and deep pathways in the ice and snow were made and produced great streams of water. (Author's abstract) W91-11394

CONCEPT OF EVAPORATION FROM FRESH AND SALINE WATER BODIES.

I. Steinhorn.
Water Resources Research WRERAQ, Vol. 27, No. 4, p 645-648, April 1991. 2 tab, 15 ref.

Descriptors: \*Evaporation, \*Salinity, \*Water level, Errors, Hydrologic budget, Temperature.

Evaporation can be described in several including mass of water molecules converted from liquid to vapor phase, mass of water evaporated per unit area, or as a decrease in water level (or downward movement of the free surface). It is demonstrated that different definitions of evaporation have different implications and meanings de-pending on the specific body of water; these definipenaling of the related equations are not inter-changeable. The error in evaporation estimates that can result from interchanging concepts incor-rectly can be up to 50%. Temperature and salinity rectty can be up to 50%. Temperature and salmity are particularly important. Evaporation results in both loss of water mass and cooling. The effect of cooling is more intensive in a saline lake for both the mass and volume units of the lake, because the energy required to evaporate water is higher. Because of volume variations due to evaporation and other heat sources, it is generally more accurate to use evaporation rate in terms of mass, which is temperature independent. For many applications, the lowering of water level, rather than the evaporation rate, is the parameter of interest. In such cases, it is suggested that the water level be regarded as the outcome of evaporation rather than considered as a measure of evaporation. (Rochester-PTT) W91-11244

RAINFALL INTERCEPTION BY TREES OF PINUS RADIATA AND EUCALYPTUS VIMIN-ALIS IN A 1300 MM RAINFALL AREA OF SOUTHEASTERN NEW SOUTH WALES: I. GROSS LOSSES AND THEIR VARIABILITY. Commonwealth Scientific and Industrial Research Organization, Canberra (Australia). Div. of Forest Pessearch.

Organization, American Research, E. W. Pook, P. H. R. Moore, and T. Hall. Hydrological Processes HYPRE3, Vol. 5, No. 2, p 127-141, April/June 1991. 6 fig, 4 tab, 24 ref.

Descriptors: \*Canopy, \*Eucalyptus trees, \*Evapo-transpiration, \*Forest ecosystems, \*Interception loss, \*Pine trees, \*Precipitation, \*Rainfall, \*Wales, Australia, Canopy storage, Model studies, Mois-ture, Rainfall intensity, Regression analysis, Stor-age capacity, Wind velocity.

Interception loss (I) is a significant proportion of the total annual evapotranspiration loss from for-ests and it varies widely between different forest types. A change of forest cover type has the impli-cation of a change in magnitude of interception

loss and corresponding predictable effects on water yield. The interception loss was determined by continuous concurrent measurements of the canopy precipitation balances of a mature seed canopy precipitation on banaces of a mature seed orchard tree of Pinus radiata and a dominant tree of Eucalyptus viminalis at a mountainous high rainfall site (900 m a.s.l.) in Tallaganda State Forest of the Upper Shoalhaven Catchment. Approximate of the Upper Shoainaven Caterment. Approximate canopy storage capacity (Sc) of the pine was 1.2 mm, and that of the eucalypt was 0.25 mm. Gross pine I was 26.5 percent and eucalypt I was 8.3 percent of the total incident rainfall over a period 18 months, from June 1975 to December 1976. The exponential model that provided the best fit to overall data relating I to gross rainfall (Pg) showed good precision for the pine (r2=0.73) but rather good precision for the pine (r2=0.73) but rather poor precision for the eucalyty (r2=0.27). A consistent pattern in interception data of the two canopy types suggested that variation in I was related to change in pervasive conditions influencing rates of evaporation from wet canopies during rainfall. Multiple regression analyses confirmed that factors such as rainfall intensity and windthat ractors such as rainfail intensity and wind-speed explained some of the variation in eucalypt, but little in pine I. Negative eucalypt I and corre-sponding low values of pine I over a wide range of Pg (up to 20 mm) suggest that capture of wind-borne precipitation (cloud, mist, or fog) had also complicated the canopy balances. (See also W91-11346) (Korn-PTT)

RAINFALL INTERCEPTION BY TREES OF PINUS RADIATA AND EUCALYPTUS VIMIN-ALIS IN A 1300 MM RAINFALL AREA OF SOUTHEASTERN NEW SOUTH WALES: II. INFLUENCE OF WIND-BORNE PRECIPITA-

Commonwealth Scientific and Industrial Research Organization, Canberra (Australia). Div. of Forest earch.

Hydrological Processes HYPRE3, Vol. 5, No. 2, p
143-155, April/June 1991. 6 fig, 3 tab, 20 ref.

Descriptors: \*Eucalyptus trees, \*Evapotranspira-tion, \*Interception loss, \*Pine trees, \*Precipitation, \*Rainfall, Australia, Canopy, Canopy storage, Clouds, Fog, Mist, Model studies, Rainfall intensity, Storage capacity, Variability, Wind velocity.

Wide variation of rainfall interception loss (I) is typical of data for storms where gross rainfall (Pg) substantially exceeds canopy storage capacity (Sc) in a variety of forests. Results of previous studies suggests that deposition of unmeasured wind-borne precipitation (i.e., drifting cloud, mist, or fog) associated with rainfall contribute to the variability of Analyses were made of the concurrent canopy precipitation balances of a seed orchard pine and a ature forest eucalypt during protracted rainfalls selected for their representativeness of the range of selected for their representativeness of the range of variation encountered in the two canopy types at Tallanganda State Forest (ca. 990 m a.s.l.) in the Upper Shoalhaven Valley of southeastern New South Wales. Although their canopy storage capacities were widely different there was consistent interception behavior in the pine and the eucalypt in all events. Detailed weather data and the time courses of interception loss provided circumstancourses of interception loss provided circumstan-tial evidence for a varying and, at times, substantial influence of cloud or mist deposition on the canopy precipitation balances during rainfall that made a significant contribution to the variation in rainfall interception data. The results of the investigation indicate a varying mitigating influence of cloud capture on the evaporative loss of rainwater from tree canopies during rainfall. This suggests that in cloud-prone environments, there is a need for careful determination of mist or cloud interception (as well as other components) to achieve more accurate descriptions of forest canopy precipitation balances. Descriptors: \*Dendrogeomorphology, \*Erosion, \*Geomorphology, \*Kentucky, \*Maxey Flats Disposal Site, \*Radioactive waste disposal, \*Slopes, Bank erosion, Data interpretation, Dendrochronology, Roots, Weathering.

A dendrogeomorphic study of slope retreat was conducted at the Maxey Flats nuclear waste disposal site in northeastern Kentucky. Tree roots exposed by surface lowering were used as an indicator of ground surface at the time of germination. The amount of lowering was measured and divided by tree ring determined age. Surface lowering and slope degradation rates were estimated for d slope degradation rates were estimated for three slopes below waste burial trenches and com-pared with data obtained from sediment troughs and erosion frames at the site. Mean rates of slope retreat ranged from 1.92 to 3.16 mm/yr. Sediment trough results are two to three orders of magnitude than dendrogeomorphic and erosion frame es timates of slope degradation, which suggests that piping and solution-weathering processes may be important factors in slope degradation. Slope aspect and declivity may be important factors affecting retreat of slopes with a uniform lithology. Dendrogeomorphic techniques provide results Dendrogeomorphic techniques provide results comparable to those in the literature and offer a rapid method for estimating slope retreat that inte-grates slope processes over many years. #### 2E. Streamflow and Runoff

COMPARISON OF NOCTURNAL DRAINAGE FLOW IN THREE TRIBUTARIES. Argonne National Lab., IL. Environmental Re-

R. L. Coulter, T. J. Martin, and W. M. Porch Journal of Applied Meteorology JAMOAX, Vol. 30, No. 2, p 157-169, February 1991. 11 fig, 3 tab, 9

Descriptors: "Colorado, "Drainage patterns, \*Mountain streams, "Streamflow, "Surface-groundwater relations, "Tributaries, "Water pollu-tion sources, Canyons, Flow, Kimball Cree, Stream banks, Stream discharge, Streams, Wind.

The characteristics of tributary drainage flow in stable, nocturnal conditions in three closely located stable, nocturnal conditions in three closely located tributaries were compared. The orientation of the tributaries with respect to Kimball Creek (Colorado), into which they drain, appeared to be a controlling factor in the tributary flow in drainage conditions was highly dependent upon the surrounding topography, its relationship to the main canyon, and local winds. Well away from the confluence of the south tributaries and Kimball Creek the designer depth was almost as deep the confluence of the south tributaries and Kimball Creek the designer death was almost as deep the confluence of the south tributaries and Kimball Creek the designer death was almost as deep the confluence of the south tributaries and Kimball Creek the designer death was almost as deep the confluence of the confluence of the south tributaries and Kimball Creek the designer death was almost as deep the confluence of the confluence of the south tributaries and Kimball Creek the designer death was almost as deep the confluence of the c Creek, the drainage depth was almost as deep as the sidewalls. Closer to the mouth, however, the depth exceeds the upwind sidewall. Because of convergence of the flows in low levels, much of nage exists 50 m and more above the surface and is quite light. In particular, oscillations in the drainage flow are found to be weakest and drainage mass per unit area greatest in the tributary most closely aligned with the main canyon. W91-10501

MONTHLY MEAN DISCHARGE AT AND BETWEEN SELECTED STREAMFLOW-GAGING STATIONS ALONG THE MISSISSIPPI, MINNESOTA, AND ST. CROIX RIVERS, 1932-87. Geological Survey, St. Paul, MN. M. E. Schoenberg, and G. B. Mitton. Available from the US Geological Survey, Books and Open-File Reports Section, Box 29425, Federal Center, Denver, CO 80225-0425. Open-File Report 90-186, 1990. 36p, 1 fig, 18 tab.

Descriptors: \*Hydrologic data collections, \*Minnesota River, \*Mississippi River, \*St Croix River, \*Stream discharge, \*Streamflow, \*Wisconsin, Flow velocity, Gaging stations.

Monthly mean discharges for the period of record are given for the streamflow-gaging stations along the upper Mississippi River from its headwaters to Prescott, Wisconsin, as well as for the first up tream streamflow-gaging station on the major tributaries of the Mississippi River, the Minnesota and St. Croix Rivers. Differences in the monthly mean discharge between selected upstream and downstream streamflow-gaging stations are given. The differences were calculated by subtracting the monthly mean discharge from the upstream streamflow-gaging station or stations from the downstream station. The difference is reported at the downstream streamflow-gaging station. (Author's abstract)

UPDATE OF FLOOD-FLOW CHARACTERIS-TICS OF NANCY CREEK AT GEORGIA HIGH-WAY 400 EXTENSION NEAR ATLANTA. GEORGIA

Geological Survey, Doraville, GA.

T. C. Stamey. Available from the US Geological Survey, Books and Open-File Reports Section, Federal Center, Box 25425, Denver, CO 8025-0425. Open-File Report 90-166, 1990. 21p, 9 fig, 3 tab, 12 ref.

The Highway Division, Georgia Department of Transportation, has proposed to extend Georgia Highway 400 from Interstate 285 southward to Interstate 85. As part of this extension, the Highway Division would construct a bridge crossing Nancy Creek near Atlanta, and relocate Nancy Nancy Creek near Atlanta, and relocate Nancy Creek at the proposed crossing. The flood-flow characteristics of Nancy Creek near the proposed bridge crossing were evaluated by the US Geological Survey as part of a study conducted in cooperation with the Highway Division. Characteristics studied include: flood frequency, elevation-discharge relations, flood profiles, floodway, and flood-flow effects. Results indicate that the maximum backwater effect for the proposed bridge and relocated channel is 0.2 ft for the 100-year flood. The proposed channel relocation will shorten the

#### Group 2E-Streamflow and Runoff

flow length near the proposed Georgia Highway 400 Extension and reduce the 100-year flood elevation between 1 and 2 feet from existing conditions between the proposed crossing and Windsor Park-way. (Author's abstract) W91-10762

ing crops, \*Stream biota, Correlation analysis, Florida springs, Light availability, Light intensity, Light penetration, Light quality, Lotic environ-ment, Nutrients, Riparian vegetation, Rivers, Streams, Submerged macrophytes, Uncertainty, egetation effects.

Florida has a large number of springs, which may represent the largest regional concentration in North America. Most of the springs create flowing water systems called spring-runs that range in size from small streams to large rivers. Previous studies on Florida springs and their associated spring-runs demonstrated that some are among the most productive lotic habitats in the world. However, others were found to be nearly anoxic and unproductive. A survey of 31 Florida spring-runs was conducted to estimate their submerged macrophyte standing crop and primary productivity. The phyte standing crop and primary productivity. The results of the investigation showed that the standing crops of submerged vegetation were not sig-nificantly correlated with either total nitrogen or total phosphorus concentrations, but were signifi-cantly correlated with the percentage of the total pinospirota concentrations, our were signifi-cantly correlated with the percentage of the spring-run's water surface shaded by marginal vegetation. Maximum daily rates of primary pro-ductivity were positively correlated with average submerged macrophyte standing crops and inversely correlated with the degree of shading by marginal vegetation. It should be noted that the marginal vegetation. It should be noted that the daily maximum production values for individual spring-runs should be regarded as relative production values because of the uncertainty associated with some of the calculations. M. Sugawara, and E. Ozaki. Hydrological Sciences Journal HSJODN, Vol. 36, No. 2, p 135-152, April 1991. 15 fig, 10 tab, 3 ref.

Descriptors: \*China, \*Discharge hydrographs, \*Flow discharge, \*Hydrologic models, \*Model studies, \*Rainfall-runoff relationships, \*Runoff forecasting, Catchment areas, Daily hydrographs, Discharge capacity, River basins, Yangtze River.

The daily discharge of the Chang Jiang (the Yangtze River) at Yichang (catchment area about one million square kilometers), downstream of Three Gorges in China, has been derived by routing the daily discharge of the Jinsha Jiang at Pringshan (catchment area about half a million square kilometers) with modeled runoff based on square kilometers) with modeled runoff based on daily precipitation at 14 rainfall stations in the downstream Sichuan basin. Precipitation at each station was transformed into runoff by means of a tank model composed with a time lag. The time lag was assumed to obey a normal distribution, the mean and the standard deviation of which were determined by the discharge on the same day at Three Gorges. Fourteen series of calculated runoffs were combined with weights to combine runoff derived from precipitation at each station in order to calculate the runoff from the Sichuan basin. The calculated Yichang discharge was derived by combining the calculated runoff from the Sichuan basin and the transformed Pingshan discharge with time lag, with weights proportional to charge with time lag, with weights proportional to the respective catchment areas. Finally, the monthly mean hydrograph and the daily hydrograph were derived by the final model. The observed and calculated monthly mean and daily discharges were found to agree closely. The River Murray in Australia discharges only 4% of annual precipitation delivered to the Murray Basin. Flow gaging and water composition data over an 18-year period (1971-1989) indicated that median annual transport of chloride out of the basin was 2.6-4.1 times that delivered annually by

#### Streamflow and Runoff-Group 2E

the atmosphere to surface runoff plus inflow from the atmosphere to surrace runoff puis minow from the tributary Darling River. The additional salt flux out of the River Murray was apparently de-rived primarily from saline groundwater plus mo-bilization by irrigation drainage of salt stored within the unsaturated zone. During March 1989, towards the end of a dry summer, the deuterium composition of water near the river mouth was -4 per thousand, compared with -43 per thousand in the largest headwater catchment. Most of this heavy isotope enrichment was the result of evapo-ration from reservoir and river surfaces plus inflow of irrigation drainage water. The trend in deuteri-um values along the river axis suggests that a large component of the chloride increase in the middle third of the river was derived from irrigation drainage whereas the further increase of chloride drainage whereas the further increase of chloride in the downstream third of the Murray was derived primarily from influx of saline groundwater. Evaporative enrichment appears to play a major role in the seasonal and geographical trends of stable isotope composition in the River Murray. The total deuterium enrichment observed indicates that integrated exponention losses in the basis in the hosting the properties of the control of the con that integrated evaporation losses in the basin are similar in magnitude to transpiration losses during the months of intensive irrigation. California Univ., Santa Barbara. Center for Remote Sensing and Environmental Optics. R. Kattelmann.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 101-110, 50

Descriptors: \*Bangladesh, \*Flood basins, \*Flood control, \*Himalayan Mountains, \*International waters, Brahmaputra River, Dams, Floods, Ganges River, India, Nepal, Reforestation.

The catastrophic flooding in Bangladesh in September 1988 largely resulted from runoff generated beyond its borders. Politicians in the region and news media around the world have blamed the high water on degraded conditions in the Himala-yan headwaters of rivers tributary to the Ganges yan headwaters of rivers tributary to the Ganges and Brahmaputra. Such claims are provoking conflict at a time when Bangladesh, India, and Nepal are involved in negotiations about the region's water resources. However, there is no scientific basis for relating the largest floods in major rivers to upstream land use. Although watershed conditions can have dramatic influences on storm flow tions can have dramatic influences on storm loop peaks of moderate frequency in small basins, rare storms of high intensity and long duration general-ly overwhelm available watershed storage. De-mands for a network of flood control dams and massive reforestation in the Himalayan foothills may avoid the more critical problems in the lowlands. Mitigation measures based on a faulty per-ception of the Himalayan hydrologic system are likely to fail. This flood controversy demonstrates the urgent need to share hydrologic data through-out the region and improve understanding of this international river system. COMPARISON OF MEAN ANNUAL RUNOFF ESTIMATES IN THE CANADIAN PORTION OF THE GREAT LAKES BASIN.

Environment Canada, Guelph (Ontario), Water Resources Branch. H. Goertz.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 159-170, 10 fig, 2 tab, 7 ref.

Descriptors: \*Annual runoff, \*Data interpretation, \*Great Lakes Basin, \*Rainfall-runoff relationships, \*Runoff forecasting, \*Streamflow, \*Water supply, Comparison studies, Hydrologic data, Precipitation, Runoff, Watersheds

A major component of the water supply to the Great Lakes is contributed from the streams and rivers in the watershed. The measurement of river rivers in the watershed. The measurement of river flows at a network of several hundred gauging stations throughout the watershed and over several years allows the quantitative assessment of various hydrologic parameters including Mean Annual Runoff, MAR. Several regional estimates of MAR for the Canadian portion of the Great Lakes Basin have been prepared since 1965. The consistency among the various MAR estimates was investigated, by comparing MAR estimates with each other and with the data of river flow gauging stations. MAR data was calculated from recorded river flow data for approximately 300 stations and extracted from the MAR maps of six previous studies. The results indicate a difference among various MAR estimates of up to 17% on average between certain studies. The results indicate a significant effect due to the period of record of data sets used certain studies. The results indicate a significant effect due to the period of record of data sets used in the calculation of MAR estimates. Under-estimation or over-estimation of MAR can impact technical designs and economic decisions. (See also W91-11003) (Author's abstract)

CHANNEL AND BANK STABILITY OF WOLF CREEK AND A TRIBUTARY AT U.S. HIGH-WAY 45 NEAR WHEELER, PRENTISS COUNTY, MISSISSIPPI. Geological Survey, Jackson, MS. Water Resources

Div K. Van Wilson, and D. P. Turnipseed. Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Open File Report 90-110, 1990. 18p, 5 fig, 3 tab, 24 ref.

Descriptors: \*Bank erosion, \*Bank stabilization, \*Channel degradation, \*Erosion, \*Wolf Creek, Channels, Streams, Vegetation.

The channel of Wolf Creek at the existing and proposed US Highway 45 relocation near Wheeler, Mississippi, has degraded about 8 ft and widened about 122 ft since it was channelized in about 1912. Channel degradation of a small tributary to Wolf Creek has totaled about 2 ft in the vicinity of the proposed relocation. Botanical evidence indicates that several recent bank failures downstream from broposed reiocation. Bolamical evidence indicates that several recent bank failures downstream from the proposed relocated crossing of Wolf Creek occurred as a result of floods in 1973, 1977, and 1987-88. Rates of channel gradation and widening-as determined from channel descriptions and botanical evidence along the banks-were used in conjunction with soil properties to estimate probable future channel degradation and widening through the year 2010. By assuming that channel bed elevations can be expressed as a power function with time, additional channel degradation hrough the year 2010 could approach 3 ft at the existing and at the proposed crossing of Wolf Creek. No further significant degradation is expected at the proposed crossing of the small tributary to Wolf Creek. The bankfull channel width of Wolf Creek at the existing and at the proposed crossing could increase about 30 ft by the year 2010. The channel width of the northern tributary at the proposed crossing could increase about 10 ft at the proposed crossing could increase about 10 ft in the next 10 to 20 years. These projections are based on the assumption that no additional channel modifications and no unusually large and destructive flooding will occur by the year 2010. (Author's abstract) W91-11107

EFFECTS OF THE 1988 DROUGHT ON WATER RESOURCES IN WISCONSIN.

B. K. Holmstrom, and B. R. Ellefson. Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Open File Report 90-149, 1990. 2p, 4 fig, 4

Descriptors: \*Drought effects, \*Hydrologic budget, \*Water deficit, \*Wisconsin, Agriculture, Domestic water, Drought, Groundwater re-sources, Industrial water, Irrigation, Municipal water, Streamflow, Surface water, Water quality, Water shortage, Water supply, Wind Lake.

The 1988 drought was one of the most severe droughts since weather records have been kept in Wisconsin; precipitation in Wisconsin was below normal in most areas during the 1988 calendar year. The statewide precipitation average of 25.7 inches for the year was 5.6 inches below the normal precipitation of 31.2 inches; 1988 was the 14th driest year since 1840. Annual runoff during the 1988 water year (October 1, 1987 to September 30, 1988) was below normal (long-term average) in the entire State, except for a few basins in south-central and southeastern Wisconsin, where runoff was 101% of normal. The water quality of many eutrophic (enriched) lakes improved because of reduced nutrient loadings. In response to this nutri-ent reduction, phosphorus concentrations in water near the lake surface declined, resulting in a substantial improvement in the lake's water quality. Record or near record low water levels were Record or near record low water levels were measured in about 50 observation wells during 1988. These low water levels are similar to those measured during the 1978 drought. The amount of water used for irrigation during 1988 increased because the drought occurred during the growing season. Groundwater accounts for approximately 98% of the water used for irrigation, and permit applications to construct new irrigation wells in 1988 increased by 95% for the period June-August. During 1988, the supply of water was usually adequate to operate all irrigation systems. Wisconsin has about 550 public water supply systems that

#### Group 2E-Streamflow and Runoff

serve approximately 65% of the State's population. Groundwater is used as a source of 495 systems and the remaining systems either purchase water form larger suppliers or use surface water. Groundwater supplies were adequate during the 1988 drought, but in many communities water use restrictions were imposed for uses such as watering lawns and washing cars. The use of surface water for self-supplied industrial and thermoelectric purposes increased during the 1988 drought, necessitating the need for some withdrawal restrictions poses increased during the 1986 drought, necessi-tating the need for some withdrawal restrictions because of low streamflow and inadequacy of sur-face water supplies. A large deficit in rainfall from April through mid-July 1988 and unusually high temperatures from June through August produced drought conditions that stressed crops and caused crop-related losses. Drought appraisals indicated that drought-related crop losses in the State in 1988 exceeded \$900 million. (Lantz-PTT) W91-11108

Descriptors: \*Channel networks, \*Dispersion, \*Geomorphology, \*Hydrodynamics, \*Hydrology, \*Rainfall-runoff relationships, \*Runoff, Catchment areas, Channel flow, Hydraulics, Model studies, Topology, Traveltime.

The hydrologic response of a channel network is defined by decomposing the process of runoff for-mulation into two distinct contributions, one ac-counting for the mechanisms of travel time within individual reaches (hydrodynamic dispersion), and the other accounting for the morphology of the network structure (geomorphological dispersion). Exact Laplace transforms of first passage time distributions at the outlet of a network are obtained by a consistent approximation of travel time distri-butions through individual reaches. The moments of such distributions are obtained analytically in the general case. Closed-form, first-passage distri-butions are obtained in the particular case of basinconstant hydrodynamic dispersion. The variance of the resulting travel time distributions is shown here to consist of two additive contributions corre sponding to the two dispersion mechanisms cons sponding to the two dispersion mechanisms considered. The geomorphologic dispersion coefficient is shown to depend on the ratios of bifurcation, length, and area of the network, suggesting that at the scale of an organized network, heterogeneities other than those related to the convection field shape the dispersive character of transport. In particular, a significant application of the general solution to Hortonian channel networks suggests that models based on accurate specification of the ge-ometry and the topology of the networks and a simplified dynamics capture the foremost features of the travel time distributions in a broad range of dispersivities within individual reaches. Two-dimensional depth-averaged mathematical models have been used to compute the flow char-acteristics in open channels with flood plains. A depth-averaged version of the kappa-epsilon acteristics in open channels with flood plants. A depth-averaged version of the kappa-epsilon model, including the term that accounts for the effect of the submerged vertical or steep boundaries on the flow characteristics in the momentum equation, was devised. Inclusion of this term plays equation, was devised. Inclusion of this term plays an important role in the distribution of the computed eddy velocity in the interaction region between the flood plain and the main channel. The results of a numerical study as well as testing of the numerical model against two sets of experimental data validated the model. Two-dimensional depth-averaged models using the kappa-epsilon turbulent shear stress can be used to predict the flow characteristics in a channel with compound cross section. In using the model, none of the empirical coefficients were tuned to match the experimental results, but were obtained from the literature. The results, but were obtained from the literature. The approximation of the friction stress on the submerged vertical wall used here proved appropri-ate. When a channel of compound cross section, comprising submerged, vertical, or steeply inclined walls, is to be modeled by a two-dimensional depth-averaged mathematical model, it is necessary to include in the momentum equation th terms that, because of the varying elevation of the channel bottom, emerged from the integration pro-cedure along the transverse direction of the horizontal momentum equations. Descriptors: \*Correction coefficients, \*Flow equations, \*Open-channel flow, \*Streamflow, \*Uniform flow, Kinetic energy, Literature review, Mathematical equations, Momentum, Theory, Velocity.

The effect of assuming uniform velocity distribution on energy and momentum considerations is a controversial problem of long history. Literature on this topic is reviewed and uniform open channel flow is considered. Experiments conducted both in model and prototype channels were used to confirm propositions going back to the 1940s. It is found both theoretically and experimentally that the kinetic energy and momentum correction coef-ficients depend significantly on the Manning roughness coefficient and that the kinetic energy correction coefficient may be related directly to the momentum correction coefficient. Further, the effect of local variation of correction coefficients is

much smaller than the variation of dynamic pres sures times the correction coefficient. Therefore, a previously proposed concept of constant coeffi-cient is justified. (Rochester-PTT) W91-11282

STREAMFLOW GENERATION IN A HEAD-WATER BASIN ON THE PRECAMBRIAN SHIELD.

Trent Univ., Peterborough (Ontario). Watershed Ecosystems Program.
C. Wels, C. H. Taylor, R. J. Cornett, and B. D.

Lazerte. Hydrological Processes HYPRE3, Vol. 5, No. 2, p 185-199, April/June 1991. 8 fig, 2 tab, 30 ref.

Descriptors: \*Headwaters hydrology, \*Overland flow, \*Rainfall-runoff relationships, \*Runoff, \*Storm seepage, \*Streamflow, Canada, Hydro-graphs, Mapping, Saturated soils, Stream discharge, Tracers.

Current conceptual runoff models hypothesize that stormflow generation on the Canadian Shield is a combination of subsurface stormflow and saturation overland flow. This concept was tested during spring runoff in a small (3.3 ha) headwater basin using isotopic and chemical hydrograph separation as well as field mapping and direct tracing of saturated areas. Isotopic and chemical hydrograph separation indicated three runoff components: (1) pre-melt subsurface flow; (2) subsurface flow of new (event) water; and (3) direct precipitation onto saturated areas (DPS). During early thawfreeze cycles, their relative contributions to total flow remained constant (65 per cent, 30 per cent, and 5 per cent, respectively). It is hypothesized that lateral flow along the bedrock/mineral soil interface, possibly through macropores, supplied large volumes of subsurface flow (of both old and new water) rapidly to the stream channel. Much higher contributions of DPS were observed during an intensive rain-on-snow event (15 per cent of total flow). Mapping and direct tracing of saturated areas using lithium bromide, suggested that saturated area size was positively correlated to stream discharge, but its response lagged behind that of discharge. These observations suggest that the runoff mechanisms, and hence the sources of stream flow, will vary depending on storm characteristics. (Author's abstract) Current conceptual runoff models hypothesize that stream flow, will vary depending on storm charac-teristics. (Author's abstract) W91-11349

STUDIES OF SPRINGS IN THE SOUTHERN PART OF THE VALLEY OF MEXICO (ESTUDIO CRENOLOGICO EN LA PARTE MERIDIONAL DE LA CUENCA DE MEXICO).

Wroclaw Univ. (Poland). Inst. Geograficzny J. Tomaszewski, R. Huizar-Alvarez, S. Marin-Cordoba, and J. Mandujano-Velazquez. Instituto de Geologia Revista RUNGD7, Vol. 8, No. 2, p 223-234, 1989. 19 fig, 2 tab, 9 ref. English

Descriptors: \*Aquifers, \*Drainage, \*Geohydrology, \*Groundwater movement, \*Mexico, \*Runoff, \*Springs, Chemical composition, Climatology, Gravity springs, Recharge, Spring water, Tectonics, Volcanic springs.

A study has been undertaken to examine the general characteristics of the different kinds of crenologic and potamologic drainage existing in the volcanic areas of the southern part of the Basin of Mexico, as well as the kind of aquifers that recharge them. The springs and runoffs are divided into several types, based on the following parameters: (1) forces causing the movement (i.e., gravity and pressure), (2) type of aquifer, (3) origin and chemical composition of the water, (4) yield variation, (5) morphology, (6) climate, and (7) tectonics of the area. The characteristics of these water discharges on the surface are described on the basis A study has been undertaken to examine the generof the area. The characteristics of these water discharges on the surface are described on the basis of the general circulation scheme of groundwater proposed for the studied area. From the hydrogeo-themical point of view, the mineral concentration is low and, therefore, the water is classified as fresh. It is concluded that the water recharging the aquifer is mainly meteoric in origin. The hydrodynamics of springs and runoff areas are analyzed on the basis of hydrologic measurements made in the field and available statistical information. This permits the grouping of the springs in the studied area into classes V, VI, and VII, based on the Meinzer classification scheme. (Author's abstract)

PALEOHYDROLOGIC TECHNIQUES USED TO DEFINE THE SPATIAL OCCURRENCE OF FLOODS.

Geological Survey, Denver, CO. R. D. Jarrett.

Geomorphology, Vol. 3, p 181-195, 1990. 12 fig, 2 tab, 28 ref.

Descriptors: \*Flood forecasting, \*Flooding, \*Floods, \*Geomorphology, \*Paleohydrology, \*Spatial variation, Flood discharge, Flood frequency, History, Hydrometeorology, Peak flow, Rainfall, Regional analysis, Streamflow.

Defining the cause and spatial characteristics of floods may be difficult because of limited stream-flow and precipitation data. New paleohydrologic flow and precipitation data. New paleohydrologic techniques that incorporate information from geomorphic, sedimentologic, and botanic studies provide important supplemental information to define homogeneous hydrologic regions. These techniques also help to define the spatial structure of rainstorms and floods and improve regional flood frequency estimates. The occurrence and the non-occurrence of naleohydrologic evidence of floods. occurrence of paleohydrologic evidence of floods, such as flood bars, alluvial fans, and tree scars, provide valuable hydrologic information. This paleohydrologic research to define the spatial characteristics of floods improves the understanding of flood hydrometeorology. This type of research was used to define the areal extent and contribut-ing drainage are of flash floods in Colorado. Paleohydrologic evidence was also used to define the spatial boundaries for the Colorado foothills region in terms of the meteorologic cause of flooding and elevation. In general, above 2300 m, peak flows are caused by snowmelt. Below 2300 m, peak flows are primarily are caused by rainfall. The foothills region has an upper elevation limit of about 2300 m. and a lower elevation limit of about 1500 m. Reand a lower elevation limit of about 1500 m. Regional flood frequency estimates that incorporate the paleohydrologic information indicate that the Big Thompson River flash flood of 1976 had a recurrence interval of approximately 10,000 yrs. This contrasts markedly with 100 to 300 yrs determined by using conventional hydrologic analyses. Flood discharge estimates based on rainfall-runoff methods in the foothills of Colorado result in larger values than those estimated with regional methods in the footnills of Colorado result in larger values than those estimated with regional flood frequency relations, which are based on long-term streamflow data. Preliminary hydrologic and paleohydrologic research indicates that intense rainfall does not occur at higher elevations in other Rocky Mountain states, and that the highest eleva-tions for rainfall-producing floods vary by latitude. REGULATORY INFLUENCE OF WATER CUR-RENT ON ALGAL COLONIZATION IN AN UNSHADED STREAM AT SHILLONG (MEGH-ALAYA, INDIA). North-Eastern Hill Univ., Shillong (India). Dept.

of Botany.
M. Ghosh, and J. P. Gaur.
Aquatic Botany AQBODS, Vol. 40, No. 1, p 37-46,
April 1991. 2 fig, 3 tab, 33 ref.

Descriptors: \*Algae, \*Colonization, \*Diatoms, \*Ecological distribution, \*Flow velocity, \*India, \*Stream biota, \*Water currents, Chlorophyll a, Ecosystems, Gomphonema, Hydrogen ion concentration, Navicula, Periphyton, Phosphorus, Physiological ecology, Population density, Riffles, Species composition, Streamflow.

The effects of current flows on periphytic algae were investigated in a spring-fed stream in Shillong (India). The experiment was carried out in March-April 1989, when there had been no rain and the stream was at its base flow. Analysis of stream water revealed a marked similarity in the chemical experiments of the need of the stream water revealed a marked similarity in the chemical stream. water revealed a marked similarity in the chemical properties of the pool and riffle zones. Initially, cell density was similar in the pool and at low flow. It declined in the pool with the lapse of time. The amount of chlorophyll a in the pool and at high flow showed no marked difference until the third week, but a slight rise occurred in the fourth week. Algal communities developing on artificial substrate in a pool as well as three riffle habitats (flow rates of 10-15, 18-22, and 37-41 cm/s) were composed only of diatoms. The stream supported scant diatom flora (27 genera in 9 species), possibly due to low pH and phosphorus-limiting conditions. In general, algal colonization was negatively related to flow rate, and was best at 10-15 cm/s. Different diatom species assumed dominance at specific flow rates: Navicula subtenelloides at 10-15 cm/s, Gomphonema parvulum and Caloneis ventricosa at 18-22 cm/s, and Synedra ulna at 37-41 cm/s. In the pool, Eunotia pseudoparallela and week, but a slight rise occurred in the fourth ventricosa at 18-22 cm/s, and Synedra ulna at 37-41 cm/s. In the pool, Eunotia pseudoparallela and Gomphonema olivaceum were most abundant. It is concluded that water current exerts a profound effect on the dynamics of algal colonization in streams. Future investigations on such algae should always define flow conditions to give the results ecological relevance. (Doria-PTT)

Descriptors: \*Benthic flora, \*Recknitz River, \*Stream biota, \*Water pollution effects, \*Water quality, Bioindicators, Germany, Species composition, Statistical analysis, Water quality monitoring.

Between August 1985 and May 1986 the bottom flora of the Recknitz River a highly polluted low-land river in the northern part of East Germany, was investigated saprobiologically. The saprobic index was calculated based on a list of species, and a statistical survey of the deviation from the arithmetic mean was made. The saprobic indices showed that conditions in the river ranged from beta-mesaprobic to polysaprobic. It was found that the calculated index may differ from the real value by a factor of 1/3 to 1/2. Investigations of microflora correlated very well with those of macroflora, indicating that the use of autotrophic organisms for the determination of water quality up to the polysaprobic level is possible. Valid results can be expected up to an alpha-mesoprobic level. (Author's abstract) thor's abstract)

Descriptors: \*Algae, \*Calcite, \*Dissolved solids, \*Streams, \*Suspended solids, \*Trapping, Aluminum, Calcium, Cyanophyta, Diatoms, England, Environmental chemistry, Geochemistry, Iron, Magnesium, Mineralization, Mineralogy, Nucleation, Organic matter, Potassium, Quartz, Silicon, Sodium, Supersaturation, X-ray diffraction, X-ray spectroscopy.

A study was undertaken to estimate the significance of the trapping and binding of suspended particles in a stream containing stromatolite-forming cyanophyta. The investigation was conducted at three sites in Waterfall Beck, North Yorkshire, England. The suspended load of the stream was determined over a one-year period and the x-ray spectra of 960 particles were analyzed. Particles were classified into six groups according to their x-ray spectra: (1) calcium only; (2) silicon only; (3) strong Al and Si plus weaker signals for any combination of Ca, Fe, K, Na, and Mg; (4) no peaks; (5) silicon peak with diatom frustule; and (6) a small residuum of diverse particles often rich in iron. The first five series of spectra represent respectively, calcite (24.5%), quartz (17.6%), aluminosilicate minerals (28.9%), organic matter (19.6%), and diatoms (3.5%). The presence of calcite and quartz was confirmed by x-ray diffraction, but no clear signals were obtained from the aluminosilicates, suggesting considerable mineralogical heterogeneity in this group. The trapping and binding of CaCO3 particles by microorganisms was shown to be negligible, with >85% of the calcite precipitated in situ. Nucleation of calcite in supersaturated water was considered to be unlikely. Results emphasized the importance of dissolved load, as compared to suspended load in limestone streams; suspended loss is about 0.1% of the dissolved loss. ESTIMATING FLOW CHARACTERISTICS AT UNGAUGED SITES.

#### Group 2E-Streamflow and Runoff

Geological Survey, Reston, VA.
H. C. Riggs.
IN: Regionalization in Hydrology. Proceedings of
the Ljubljana Symposium, April 1990. IAHS Publication No. 191, 1990. p 159-169, 3 fig. 2 tab, 14

Descriptors: \*Stream gaging. \*Streamflow fore-casting. \*Data interpretation, \*Streamflow, \*Model studies, \*Flow characteristics, Interpola-tion, Mathematical analysis, Drainage area, Slope, Precipitation, Peak flow, Regression analysis.

Given a network of gaging stations and data on the climatic and physical characteristics of drainage basins in the region, one can relate flow characteristics to basin characteristics and use the relation to estimate flow characteristics at ungaged sites. The commonly used log linear model produces a relation that is homoscedastic—that is, the standard error is the same throughout the ranges of the independent variables. A problem in applying the log linear model arises when the value of a variable for some basis is zero, for which there is no real logarithm. This can be overcome by adding a small constant to all the values of that particular variable before using the variable in regression. Many basis and climatic characteristics have been proposed and used, and in the desire to attain the smallest standard error of regression, the analyst may pu many characteristics in a regression and use all those that are found to be statistically significant. Drainage area, channel slope, storm precipitation for some duration and recurrence interval, and surface storage are known to affect flood peak characteristics. For mean flow, the principal characteristics are drainage area and annual precipitation. If a basin characteristic, such as channel ston. It a basic characteristic, such as channel slope, has nearly the same value for all streams in a region, its regression coefficient would not be statistically significant and slope should be eliminated from the regression. The reliability of a regional from the regression. The retability of a regional relation, or even its validity in a particular region, will depend on the quality of the streamflow data, the homogeneity of the region hydrologically, and the adequacy of information about the basin. Streamflow records, and thus flow characteristics, are commonly available at intervals along large streams. Better estimates between gaged sites can be made by interpolation than by other methods, particularly in semiarid regions in which not all parts of the drainage basin contribute equally or at the same time. Interpolation of flood characteristics between gaged sites on a channel is by trial, using the assumptions that appreciably increase occur only where tributaries enter. Discharge is occur only where tributaries enter. Discharge is plotted against channel length because this format allows for marking identifiable points along the channel so that a user can readily identify his point of interest. The result is most reliable where low flow characteristics of tributaries are available. (Lantz-PTT) W91-11545

SHORT-TERM EFFECTS OF A CATASTROPHIC BEAVER DAM COLLAPSE ON A STREAM FISH COMMUNITY.

S. D. Succk, and I. J. Schlosser.
Environmental Biology of Fishes EBFID3, Vol. 31, No. 2, p 123-129, June 1991. 3 fig, 14 ref, append. NSF Grant Nos. BSR 8320371 and BSR 8804926.

Descriptors: \*Dam failure, \*Flash floods, \*Stream fisheries, \*Beaver dams, \*Benthic fauna, Riffles, Insects, Ecosystems, Species diversity, Population dynamics, Fish populations.

The catastrophic collapse of a beaver dam and the ensuing flash flood, in a headwater tributary of the Mississippi River, resulted in a dramatic (> 90%) ensuing hash floods, in a fleaturater tribitary of the Mississippi River, resulted in a dramatic (> 90%) decrease in benthic insect density in riffle and pool habitats. Sixty days after collapse of the dam, insect densities in riffles were 62% of pre-collapse densities. Insect recolonization of pools was slower than for riffles; 60 days after collapse of the dam insect densities in pools were 8% of pre-collapse levels. Collapse of the beaver dam altered the structure of the downstream fish community by causing a short-term (2-4 days) influx of pond

species, resulting in a brief increase in species richness and abundance. Fish species richness and abundance then decreased for 4-60 days to levels below those prior to the collapse. (Author's ab-

DESCRIPTION OF THE PHYSICAL ENVI-RONMENT AND COAL-MINING HISTORY OF WEST-CENTRAL INDIANA, WITH EMPHASIS ON SIX SMALL WATERSHEDS.

J. D. Martin, C. G. Crawford, R. F. Duwelius, and

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Supply Paper 2368, 1990. 38p, 24 fig, 10 tab. 40 ref.

Descriptors: \*Coal mining, \*Geohydrology, \*Groundwater pollution, \*Groundwater quality, \*Water pollution sources, Agriculture, Aquifers, Eel River Basin, History, Pond Creek, Rainfallrunoff relationships, Soil types, Wabash River Basin, White River Basin.

West-central Indiana is underlain by coal-bearing Pennsylvanian rocks. Nearly all of the area has been glaciated at least once and is characterized by wide flood plains and broad, flat uplands. Most of the soils have formed in loess or in loess overlying Illinoian till. The Wabash, White, and Eel Rivers are the major drainages in west-central Indiana. Average annual precipitation is about 13 n/5 inches/y, and average annual runoff is about 13 n/5. The most productive aquifers are confined or unconfined outwash aquifers located along the major rivers. Bedrock aquifers are regionally insigificant but are the sole source of groundwater for areas that lack outwash, alluvium, or sand and gravel but are the sole source of groundwater for areas that lack outwash, alluvium, or sand and gravel lenses in till. Indiana has > 17 billion short tons of recoverable coal reserves; about 11% can be mined by surface methods. Almost half of Indiana's surface reserves are in Clay, Owen, Sullivan, and Vigo Counties. More than 50,000 acres in west-central Indiana were disturbed by surface coal mining from 1941 through 1980. The unnamed tributary to Honey Creek and the unnamed tributary to Sulfur Creek are streams that drain mined and reclaimed watersheds. Ridges of mine spoil have been graded to a gently rolling topography. Soils are well drained and consist of 6 to 12 inches of silt-loam topsoil that was stockpiled and then onis are well crained and consist of 0 to 12 incnes of silt-loam topsoil that was stockpiled and then replaced over shale and sandstone fragments of the graded mine spoil. Grasses and legumes form the vegetative cover in each watershed. Pond Creek vegetative cover in each watershed. Pond Creek and the unnamed tributary to Big Branch are streams that drain mined and unreclaimed watersheds. Approximately one-half of the Pond Creek watershed is unmined, agricultural land. Soils are very well drained shally silty loams that have formed on steeply sloping spoil banks. Both watersheds contain numerous impoundments of water and have enclosed areas that do not contribute surface runoff to streamflow. The ridges of mine poil are covered with pine trees but much of the spoil are covered with pine trees, but much of the soil surface is devoided of vegetation. (See also W89-08987) (Lantz-PTT)

DELINEATION OF FLOODING WITHIN THE OZARK NATIONAL SCENIC RIVERWAYS IN SOUTHEASTERN MISSOURI-AKERS AND ALLEY SPRING.

# POINT-INFILTRATION MODEL FOR ESTI-MATING RUNOFF FROM RAINFALL ON SMALL BASINS IN SEMIARID AREAS OF

J. G. Rankl.

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Supply Paper 2366, 1990. 29p, 21 fig, 12 tab, 15 ref.

Descriptors: \*Infiltration, \*Mathematical models, \*Rainfall-runoff relationships, \*Semiarid lands, \*Wyoming, Drainage, Ephemeral streams, Runoff, Soil water, Storm runoff.

A physically based point-infiltration model was developed for computing infiltration of rainfall into soils and the resulting runoff from small basins in Wyoming. The user describes a 'design storm' in terms of average rainfall intensity and storm duration. Information required to compute runoff Wyoming. The user describes a 'design storm' in terms of average rainfall intensity and storm duration. Information required to compute runoff for the design storm by using the model include: (1) soil type and description; and (2) two infiltration parameters and a surface retention storage parameter. Parameter values are tabulated in the report. Rainfall and runoff data for three emphemeral stream basins that contain only one type of soil were used to develop the model. Two assumptions were necessary: antecedent soil moisture is some long-term average, and storm rainfall is uniform in both time and space. The infiltration and surface retention storage parameters were determined for the soil of each basin. Observed rainstorm and runoff data were used to develop a separation curve, or incipient-runoff curve, which distinguishes between runoff and nonrunoff rainfall data. The position of this curve defines the infiltration and surface retention storage parameters. A procedure for applying the model to basins that contain more than one type of soil was developed using data from 7 of the 10 study basins. Analyses of runoff from multiple-soil basins indicate that the effective contributing area of runoff is less than the drainage area of the basin. In this study, the effective drainage area. A comparison was made of the sum of the sum of the the total drainage area. A comparison was made of the sum of the simulated runoff and the sum of the the sum of the simulated runoff and the sum of the measured runoff for all available record of runoff-producing storms in the 10 study basins. The sums of the simulated runoff ranged from 12% less than to 23.4% more than the sums of the measured runoff. A measure of the standard error of estimate was computed for each data set. These values ranged from 20-70% of the mean value of the measured runoff. Rainfall-simulator infiltrometer tests were made in two small basins. The amount of water uptake measured by the test in Dugout Creek tributary basin averaged about three times greater than the amount of water uptake computed from rainfall and runoff data. Therefore, infiltrometer data were not used to determine infiltration rates for this study. (Lantz-PTT) W91-11585

ANALYSIS OF ALTERNATIVE MODIFICA-TIONS FOR REDUCING BACKWATER FLOODING AT THE HONEY CREEK COAL STRIP MINE RECLAMATION SITE IN HENRY COUNTY, MISSOURI.

Geological Survey, Rolla, MO. Water Resources Div.

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 90-4068, 1990. 22p, 12 fig. 5 tab, 14 ref.

Descriptors: \*Backwater, \*Backwater floods, \*Channel improvement, \*Coal mining, \*Flood control, \*Honey Creek Basin, Channel flow, Flooding, Flow velocity, Missouri, Model studies, Runoff, Surface water.

Studies to determine the hydrologic conditions in mined and reclaimed mine areas, as well as areas of proposed mining, have become necessary with the enactment of the Surface Mining Control and Reclamation Act of 1977. Honey Creek in Henry County, Missouri, has been re-routed to flow through a series of former strip mining pits which lie within the Honey Creek coal strip mine recla-mation site. During intense or long duration rain-falls within the Honey Creek basin, surface runoff caused flooding on agricultural land near the up-stream boundary of the reclamation site. A hydro-logic and hydraulic investigation was conducted for part of the Honey Creek basin and its adjacent for part of the Honey Creek oalsn and its augment area to evaluate the strip mining related causes of backwater flooding and possible means of alleviat-ing future flooding. The calculated existing design discharge (3,050 cu ft/s (cfs)) water surface profile is compared to the expected water surface profiles. from three assumed alternative channel modifica-tions within the Honey Creek study area. Empha-sis is placed on evaluating the potential effects of each alternative to reduce water surface elevations (backwater flooding) along the upstream boundary of the Honey Creek reclamation site near an agricultural field. The alternative channel modifications used in these analyses include: (1) improvement of channel bottom slope; (2) relocation of ment of channel bottom slope; (2) relocation of spoil material; and (3) improved by-pass channel flow conditions. Study results indicate a 0.39, 0.43, and 0.30 foot backwater reduction at the agricultural field based on the assumed channel modifications of alternatives 1, 2, and 3. Several combinations of these alternatives were analyzed, and in each case the reduction in backwater flooding was numerically equal to the sum of their individual decreases. The concurrent water surface elevation of reduction (1.12 ft) of alternative 1 (design discharge increase of 400 cns), alternative 2 (design discharge increase of 400 cns). of reduction (1.12 ft) of alternative 1 (design discharge increase of 400 cps), alternative 2 (design discharge increase of 600 cps), and alternative 3 (design discharge increase of 250 cps) can be converted into a Honey Creek design discharge increase from 3,050 cps to 4,300 cps. Thus, the alternative 1, 2, and 3 design discharge increase will reduce the agriculturarl field current (1990) frequency of backwater flooding from a 3-yr to a 6.5-yr event. The International Ground Water Modeling Center (GWMC) has established a Groundwater Research (GWMC) has established a Groundwater Research Data Center which provides information on research datasets resulting from publicly funded field experiments regarding soil and groundwater pollution and related laboratory bench studies, and which distributes selected public domain datasets for testing and validation of models for flow and conteminant transport in the saturated and unsature. contaminant transport in the saturated and unsatu-rated zones of the underground. To fulfill its advisory role, the Data Center analyzes information and documentation resulting from field and labora-tory experiments, and evaluates the appropriate datasets for their suitability in model testing and validation. (The Center has identified validation as the major secondary use of such data). To assure consistency in the analysis and description of these datasets, and to provide an efficient way to search, retrieve, and report information on these datasets, the Data Center has developed a computerized data directory, SATURN, programmed independently from any proprietary software. As secondary users of such soil water and groundwater data are highly interested in information relevant to the assessment of data quality, a primary concern of the Center is the evaluation and documentation of the level of quality assurance applied during data acquisition, data handling, and data storage. In addition to providing referral services, the Data Center distributes, on an 'as-is' basis, selected, high quality datasets described in the data directory. The datasets of concern represent different hydrological, geological, and geographic-climatic set-tings, pollutant compositions, and degrees of con-tamination. (Lantz-PTT) W91-10736

GEOHYDROLOGIC EVALUATION SPRING SITES AT SOCIAL CIRCLE, GEOR-GIA, DECEMBER 5-8, 1988.

Geological Survey, Doraville, GA

I S Clarke

Available from the US Geological Survey, Books and Open-File Reports Section, Box 25425, Feder-al Center, Denver, Co 80225-0425. Open-File Report 89-236, 1989. 18p. 7 fig. 1 tab, 13 ref.

Descriptors: \*Drawdown, \*Geohydrology, \*Georgia, \*Groundwater management, \*Groundwater yield, \*Springs, \*Water yield, Aquifers, Catchment areas, Groundwater recharge, Groundwater resources, Pumping, Recharge.

Two springs in the Piedmont physiographic province at Social Circle, Georgia, were evaluated to determine their geohydrologic characteristics, estimated recharge, and maximum sustained yield. Aquifer tests indicated that the springs respond to pumping in a manner similar to bored wells in the Piedmont. At the lower spring, a pronounced water level response to rainfall indicates that it is under water table conditions. Recharge to the water table is believed to be limited to a 0.18 sq mi under water table conditions. Recnarge to me water table is believed to be limited to a 0.18 sq mi under water table conditions. Recharge to the water table is believed to be limited to a 0.18 sq mi drainage basin upgradient of the lower spring. The small drainage area and an estimated annual recharge rate of 6.5 inches indicates that the potential yield to the springs averages about 55,690 gallons per day (gpd). The 13-foot deep lower spring was the most productive, sustaining yields of between 60 and 94 gpm during much of a 25-hour aquifer test. Sluggish recovery during the last 11% of drawdown may indicate: (1) a water level decline due to below normal rainfall, (2) that pumping from the upper spring intercepted recharge to the lower spring, or (3) that some water was removed from groundwater storage during the aquifer tests. The 21-foot deep upper spring was pumped at rates ranging from 34 to 83 gpm, and was able to sustain yields of 34 to 40 gpm during a 25-hour aquifer test. At a rate of 34 gpm, drawdown in the spring reservoir stabilized at about 62% of the available drawdown, which was probably close to the maximum sustained yield. Although results of the two tests indicate that the combined yield of the two tests indicate that the combined yield of the two tests indicate that the though results of the two tests indicate that the combined yield of the two springs ranged from about 135,360 to 184,320 gpd in December 1988, it is doubtful that a combined pumping rate in excess of the estimated average potential yield of the drainage basin (55,690 gpd) could be maintained on a natural basis. As intermittent pumping schedula an annual basis. An intermittent pumping schedule allows for pumping at a higher rate at peak demand periods and at lower rates during periods of low demand. CHARACTER AND EVOLUTION OF THE GROUND-WATER FLOW SYSTEM IN THE CENTRAL PART OF THE WESTERN SAN JOAQUIN VALLEY, CALIFORNIA.

K. Belitz, and F. J. Heimes. Available from the US Geological Survey, Books and Open-File Reports Section, Box 25425, Feder-al Center, Denver, Co 80225-0425. Water-Supply Paper 2348, 1990. 28p, 24 fig, 31 ref.

Descriptors: \*Geohydrology, \*Groundwater movement, \*Groundwater resources, \*San Joaquin Valley, Agriculture, Aquifers, Confined aquifers, Flow pattern, Groundwater irrigation, Groundwater mining, Groundwater quality, Groundwater recharge, Percolation, Potentiometric surface, Water use.

The occurrence of selenium in agricultural drain water derived from the western San Joaquin Valley, California, has focused concern on the groundwater flow system of the western valley. Previous work, and recently collected texture and Previous work, and recently collected texture and water level data, are used to evaluate the character and evolution of the regional groundwater flow system in the central part of the western valley. Particular emphasis is placed on the deposits overlying the Corcoran Clay Member of the Tulare Formation, which presently divides the flow system into an upper semiconfined zone and a lower confined zone. Above the Corcoran, three hydrogeologic units can be recognized: Coat Ranges alluvium, Sierran sand, and flood-basin deposits. These units differ in texture, hydrologic properties, and oxidation state. The development of irrigated agriculture in the central part of the western valley has significantly altered the flow system. Percolation of irrigation water past crop roots has caused a rise in the altitude of the water table in midfan and distal-fan areas. Pumpage of table in midfan and distal-fan areas. Pumpage of groundwater from wells has caused a lowering of he water table beneath parts of the fanheads and a the water table beneath parts of the fanheads and a lowering of the potentiometric surface of the confined zone over much of the western valley. The combination of percolation and pumpage has resulted in the development of a large downward hydraulic head gradient in the semiconfined zone and has created a groundwater divide. Surface water deliveries from the California Aqueduct have allowed a decrease in numning and a consehave allowed a decrease in pumping and a conse-quent recovery in hydraulic head throughout the system. New analyses of the isotopic composition of water, 14C-dating of dissolved carbon, and order-of-mag-nitude Darcy calculations suggest that a dilute nitude Darcy calculations suggest that a dilute body of water, trending north-south in the Cambri-an-Ordovician aquifer of Iowa, was emplaced as vertical recharge of Pleistocene-age water from the base of the Des Moines lobe of late Wisconsin time. The recharge occurred through more than 300 m of overlying Silurian to Mississippian age rocks. The delta 180 values range from -10 ppt to -90 ppt for the dilute water body and are consistent with a mixture of Des Moines lobe meltwater and

#### Groundwater-Group 2F

precipitation having an isotopic content similar to or heavier than that of average precipitation found today in the north-central United States. These results suggest that (1) the climate at the end of last glaciation was mild, and (2) a groundwater stable isotope signature similar to that of modern precipitation in an aquifer's recharge area is not a priori evidence for relatively recent recharge. MUNICIPAL GROUND WATER FROM ANCIENT CRYSTALLINE BEDROCK. Caswell, Eichler and Hill, Inc., West Topsham, B. Caswell.

Water Well Journal WWJOA9, Vol. 45, No. 5, p 44-48, May 1991. 5 fig.

Descriptors: \*Crystalline rocks, \*Geohydrology, \*Geologic fractures, \*Groundwater resources, Descriptors: "Crystalline rocks, "Geohydrology, "Geologic fractures, "Groundwater resources, "Municipal water, "Water resources development, "Water supply development, Bedrock, Explora-tion, Geological surveys, Groundwater availabil-ity, Groundwater recharge, Pumping tests, Well construction."

Hydrogeologists generally do not consider the crystalline rock types of the Adirondack Mountain area of New York as a significant groundwater area of New York as a significant groundwater resource because groundwater is available only from fractures in the bedrock. A case study was undertaken in the Adirondack Mountains of New York where a municipal groundwater supply was sought to replace a lake source that could not meet federal drinking water standards without costly treatment. Groundwater exploration identified apparent bedrock fracture zones through interpretation of topographic maps, satellite imagery, and geophysics. The results of the study revealed that ancient crystalline bedrock, where well fractured, can furnish significant supplies of high-quality groundwater. The key seems to be the location of transmissive fractures where a high-yield well can be constructed, and siting wells in hydrogeologic settings that afford ample recharge in underlying bedrock fracture systems. However, similarly favorable recharge conditions may not be available everywhere in the ancient crystalline bedrock ternain of North America. Furthermore, there are too rain of North America. Furthermore, there are too few high-yield wells in the Adirondack Mountains to verify that topographic lineaments everywhere reveal water-bearing bedrock fractures. It should also be noted that the same lineaments may repreasso be lotted that the same intendences may represent highly preferential pathways for contaminant migration in crystalline bedrock terrain. A study was conducted on three peat profiles from the Lost River Peatland, Minnesota, to test the extent to which the metal content of peat is modified by active groundwater flow and the extent to which it can be used to locate groundwater discharge. It was found that major variations in the concentrations of the base cations Ca, Mg, Sr, and the minor metals Fe and Na in peat profiles from the Lost River Peatland are mostly related to the the Lost River Peatland are mostly related to the geochemical environment caused by groundwater discharge into the peat, rather than to differences in anthropogenic atmospheric loadings or the original chemical composition of the peat at the time of deposition. Elevated concentrations of metals in the peat profile, particularly from a spring-fen, identify where the greatest volume of groundwater discharge occurs in the peatland. In each profile, the metal content of the peat corroborates previous hydrologic and geochemical studies each profile, the metal content of the peat corroso-rates previous hydrologic and geochemical studies showing active groundwater flow in the humified peat, which must have substantial permeability. Consequently, metal profiles in peat may be used as indicators of the conditions of groundwater flow in peatlands where other hydrologic or geochemi-cal information is lacking. A simplified approach to reduce a time-variant problem into a steady-state problem is considered by averaging the groundwater head over a season-al period. This averaging is applicable to those areas (countries) where a year can be divided into three distinct periods; monsoon, pre-monsoon, and post monsoon; and where the annual water table post monsoon; and where the annual water table variation is not large compared with the saturated aquifer thickness. This scheme was applied to solve a two-dimensional problem using a standard finite difference technique of solution. The phreatic aquifer system considered is bounded by two reservoirs and an impervious base. It also contains a partially protected the souther of t penetrating river near the center of the aquifer. penetrating river near the center of the adjunc-periodic contribution to the phreatic aquifer from the higher head reservoir, groundwater recharge from river seepage, net-free surface flux and the total groundwater flow towards the lower head reservoir are worked out were determined. The analysis of the flow curves reveals that the lowering in the total flow values from monsoon to post-monsoon and pre-monsoon is caused primarily by a decrease in the net-free surface flux values, seconddecrease in the net-tree surrace hux values, second-ly by a reduction in the flow contributions from the higher head reservoir and finally and of least significance, by the river contributions which show a minimum variation with seasonal changes show a minimum variation with seasonal changes in weather. The study shows that on a yearly basis 64.6% of the total available groundwater is contibuted by effective annual free surface flux and 29.2% by the higher head reservoir, while only 6.2% is added from river seepage. These terms aid in estimating the net volume of groundwater that is available from the aquifer system in a particular seasonal period. (Agostine-PTT) W91-10910

#### Group 2F-Groundwater

Both response matrix and embedding techniques are commonly used to compute optimal sustained-yield groundwater extraction strategies for con-fined aquifers. Historically, the response matrix method has been considered the most practical, because of numerical instability reported to occur when using the explaciding expressions. because of numerical instability reported to occur when using the embedding approach for large aquifer systems. More recent studies have proven the embedding approach to be stable for large-scale regional planning. Also, there is increasing emphasis on using microcomputers for groundwater studies. Thus, it is appropriate to compare response matrix and embedding approaches to steady-state problems in terms of computational efficiency and memory requirements. For the hypothetical study area, a steady-state embedding model requires less area, a steady-state embedding model requires less processing time than a comparable response matrix model. In addition, the embedding model sometimes requires less memory than a response matrix model. Required computer memory is frequently a function of the number of nonzero values in con-straint equations. For embedding models, the number of nonzeroes is fixed for a particular study area. For response matrix models, the number of area. For response matrix modes, the number of nonzeroes can increase dramatically in proportion to the number of pumping cells and cells at which heads must be constrained. For the sample system, if more than 25% of the cells can pump, the If more than 25% of the cells can pump, the response matrix approach requires more memory than does the embedding approach. Before selecting an optimization model for a particular study, one should, evaluate potential memory requirements of both embedding and response matrix approaches. If there is a high percentage of pumping cells, or if many heads must be constrained or computed within the confinitestion model the or computed within the optimization model, the em-bedding approach seems preferable. DELINEATION OF TRAVELTIME-RELATED CAPTURE AREAS OF WELLS USING ANA-LYTICAL FLOW MODELS AND PARTICLE-TRACKING ANALYSIS.

Ohio State Univ., Columbus. Dept. of Geology

and Mineralogy. E. S. Bair, A. E. Springer, and G. S. Roadcap. Ground Water GRWAAP, Vol. 29, No. 3, p 387-397, May/June 1991. 17 fig. 13 ref.

Descriptors: \*Aquifer properties, \*Flow models, \*Groundwater movement, \*Model studies, \*Pumping tests, \*Well hydraulics, Flow measurement, Geohydrology, Traveltime, Well data, Well fields, Well pumping.

Traveltime-related capture areas of wells can be estimated in hydrogeologic settings with predominantly two-dimensional flow regimes using image-well theory, the principle of superposition, an appropriate well-hydraulics equation, and particle-tracking analysis. These analytical methods can be used to simulate the response of an aquifer to pumping stress by incorporating site-specific values of hydraulic properties, the effects of geologic and hydrologic boundaries, nonuniform regional hydraulic gradients, and well interferences. This is done by developing a conceptual model of the flow system, incorporating an image-well solution (if needed), computing drawdowns at the intersections of a rectangular grid superposed over the area of interest, and subtracting computed microcctions of a rectangular grid superposed over the area of interest, and subtracting computed drawdowns from regional prepumping head values assigned to the grid intersections. The resulting flow model can be calibrated by comparing pre-dicted heads with measured heads. The calibrated head distribution then is used in a particle-tracking analysis to determine flowpath trajectories and traveltime-related capture areas of wells. Analyti-cal flow models based on the Theis equation and the Hantush-Jacob equation were constructed from conceptual flow models based on geologic, hydrologic, and pumpage data from wellfields completed

in a confined/unconfined stratified-drift aquifer and in a leaky-confined fractured-carbonate aquifer. Predicted head distributions from the calibrat-ed flow models were used in a particle-tracking analysis to compute flowpath trajectories and trav-eltime-related capture areas. The results compare favorably with known flowpaths from sources of contamination proximal to each wellfield. (Author's abstract) W91-10957

TRITIUM AS AN INDICATOR OF GROUND-WATER AGE IN CENTRAL WISCONSIN.

Wisconsin Geological and Natural History Survey, Madison.

K. R. Bradbury. Ground Water GRWAAP, Vol. 29, No. 3, p 398-404, May/June 1991. 6 fig, 3 tab, 15 ref.

Descriptors: \*Groundwater chemistry, \*Groundwater dating, \*Tritium, \*Wisconsin, Glacial soils, Groundwater data, Groundwater movement, Groundwater recharge.

In regions where groundwater is generally younger than about 30 years, developing the tritium input history of an area for comparison with the current tritium content of groundwater allows quantitative estimates of minimum groundwater age. The tritium history for central Wisconsin has age. The tritium instory for central wisconsin has been constructed using precipitation tritium measured at Madison, Wisconsin, and elsewhere. Weighted tritium inputs to groundwater reached a peak of over 2,000 tritium units (TU) in 1964, and have declined since that time to about 20-30 TU at present. In the Buena Vista basin in central Wis-consin, most groundwater samples contained ele-vated levels of tritium, and estimated minimum groundwater ages in the basin ranged from less groundwater ages in the basin ranged from less than one year to over 33 years. Groundwater in mapped recharge areas was generally younger than groundwater in discharge areas, and estimated groundwater ages were consistent with flow system interpretations based on other data. Esti-mated minimum groundwater ages increased with mated minimum groundwater ages increased with depth in areas of downward groundwater movement. However, water recharging through thick moraine sediments was older than water in other recharge areas, reflecting slower infiltration through the sandy till of the moraine. (Author's W91-10958

DEPTH OF FRACTURES AND ACTIVE GROUND-WATER FLOW IN A CLAYEY TILL PLAIN IN SOUTHWESTERN ONTARIO. Waterloo Univ. (Ontario). Inst. for Ground Water

W. W. Ruland, J. A. Cherry, and S. Feenstra. Ground Water GRWAAP, Vol. 29, No. 3, p 405-417, May/June 1991. 9 fig, 3 tab, 27 ref.

Descriptors: \*Canada, \*Clay soils, \*Geologic fractures, \*Groundwater movement, \*Ontario, \*Tritium, Aquifer characteristics, Hydraulic conductivi-ty, Water table fluctuations.

The St. Clair Plain in southwestern Ontario is underlain by extensive clayey till deposits which are generally 30 m to 40 m thick. The tills have vertical fractures near the ground surface, and the depth of those fractures has been investigated. Observations in test pits show that most weather-Observations in test pits snow that most weather-ing features along fractures reach a depth of only 2.5 m to 4 m, though isolated major fractures extend past the pit bottom depth of 5.6 m at two sites. The depth of active groundwater flow, which is defined as the groundwater flow in the clayey deposit which occurs in fractures, was also investigated. Water such account a state shows bulk investigated. Water-level response tests show bulk hydraulic conductivities of the fractured till ranging from >0.0000001 to 0.0000001 cm/s. Seasonal variations in hydraulic head profiles suggest that fractures influence groundwater flow to maximum depths ranging from 5 m to more than 10 m at the 10 sites studied. The water table is usually within 2 To sites studied. The water table is usually within 2 m of the surface, but piezometers went dry to depths of 2 m to 4.9 m during dry periods in 1987 and 1988. Tritium levels greater than 1 tritium unit (TU), indicating the presence of post-1952 water, are found to depths of 7.5 m at all sites and to

depths exceeding 12 m in two cases. Tritium has moved to the base of deep, open fractures by active groundwater flow and has travelled 1 or 2 m beyond that depth by molecular diffusion. Observations of seasonal water-level variations and tritium sampling show the most promise for determining the maximum depth of hydraulically active, vertical fractures. The maximum depth of active consedures flow in features were widely range. groundwater flow in fractures varies widely, ranging from 5 m to more than 10 m at the 12 sites studied on the St. Clair Plain. #### Groundwater—Group 2F

Descriptors: \*China, \*Confined aquifers, \*Environmental tracers, \*Groundwater movement, \*Groundwater recharge, \*Isotope studies, \*Leaky aquifers, \*Seepage, Carbon radioisotopes, Deuterium, Flow measurement, Flow models, Flow velocity, Groundwater runoff, Isotopic tracers, Oxygen isotopes. isotopes, Tritium.

A detailed study of the prediction and management of groundwater and the environment, employing new methodologies and new techniques, was started in Shaanxi Province in China in 1986, using environmental isotope techniques to trace groundwater sources, leakage among aquifers, and recharge of runoff to confined aquifers. Ninety-six water samples were collected in the Xi'an area and analyzed for D, T, 18-Q, and 14-C. Stable isotope contents of water samples from three aquifers show differences between, and mixing among, the three aquifers; the mixing ratio was 37.4% of phreatic water in the first confined aquifer and 43.8% of first mixed water to the second mixed water in the second confined aquifer. The phreatic water comprised about 43.8% x 37.4% = 16.4% of the second mixed water in the second confined aquifer. After the tritium contents in precipitation in the Xi'an regions had been reconstructed by a multiple and lighter except in the second confined aquifer. the second mace was a superstance of the Xi'an regions had been reconstructed by a multiple cell linear regression method, the ground-water velocity in the first confined aquifer was calculated as 30-39 m/yr from an exponential flow model. A 14-C piston flow model gave estimates of average flow velocity in the second confined aquifer of 1.14/yr. The runoffs in the two aquifers were calculated, but they are not the total recharge also calculated, but they are not the total recharge from the pluvial fan to the center of the cone of depression around Xi'an city; the width of re-charge must be known for this calculation. From the analyses of stable isotopes, radioisotopes, and hydrogeological conditions of thermal groundwater in front of the mountain, it seems that deep circulation is occurring from the mountain area to the second confined aquifer through an existing deep fault in front of Qing Mountain. Another possibility is that the second confined water was buried in paleoclimatic conditions and was mixed paleoclimatic conditions and was mixed with infiltrating younger surface water or mountain runoff, because of its high age and low tritium content. Descriptors: \*Advection, \*Groundwater move-ment, \*Groundwater transport, \*Hydrologic models, \*Model studies, \*Path of pollutants, \*Solute transport, Boundary processes, Flow models, Flow velocity, Injection wells, Well pumping

One of the most crucial factors that affects both One of the most crucial incross that allects soon the accuracy and efficiency of a groundwater transport model is the flow simulation method which produces the velocity field. A boundary element technique has been developed which inelement technique has been developed which in-corporates the zoning approach to allow aquifer heterogeneity. First, the accuracy of the flow model is verified by comparing it with analytic solutions for well-pumping and injection problems. The boundary element flow model is then coupled with a particle tracking procedure for advection-based transport simulation. The combined model also calculates streamlines, travel times, and break-through curves and is the travel times, and breakand oreas streammes, traver times, and breast-through curves and is therefore a powerful tool for simulation and management of advection-dominat-ed contamination problems. A series of tests against analytical solutions, especially near interzonal boundaries, shows that the numerical errors produced are not significant, are explicable, and are easily controllable by simple means such as local grid refinement and use of small time steps. A realistic application of the coupled model emphasized its utility in solving real-life engineering problems. (Fish-PTT) W91-10997

DISCRETE-KERNEL METHOD FOR SIMULATING PUMPING TESTS IN LARGE-DIAMETER WELLS.

British Geological Survey, Wallingford (England). J. A. Barker.

Journal of Hydrology JHYDA7, Vol. 124, No. 1/
2, p 177-183, April 1991. 1 fig, 2 tab, 6 ref.

Descriptors: \*Hydrologic models, \*Model studies, \*Pumping tests, \*Theis equation, \*Well function, Error analysis, Well hydraulics, Well pumping.

The discrete-kernel method, as previously employed, incorrectly used the Theis well function rather than the well function for a large-diameter well without storage. Use of the Theis function and small time steps gives errors that oscillate in sign and grow exponentially with time. An approximation to this latter function, suitable for computation, has been developed so that existing codes may be readily corrected. The instability can be overcome by replacing the Theis function. be overcome by replacing the Theis function by the well function for a well of finite diameter but no storage. This replacement function ensures sta-bility for small time steps and increases the accura-cy of the method. (Fish-PTT) W91-10998

MAPS OF THE '400-FOOT,' '600-FOOT,' AND ADJACENT AQUIFERS AND CONFINING BEDS, BATON ROUGE AREA, LOUISIANA. Geological Survey, Baton Rouge, LA. Water Re-

Sources Div.

E. L. Kuniansky, D. C. Dial, and D. A. Trudeau.

State of Louisiana Water Resources Technical
Report No. 48, 1989. 16p, 4 fig, 1 tab, 9 plates, 29

Descriptors: \*Aquifer systems, \*Baton Rouge, \*Confined aquifers, \*Hydrologic data collections, \*Louisiana, \*Maps, Aquifers, Clays, Geohydrology, Groundwater management, Groundwater mining, Hydraulic conductivity, Model studies, Pumping, Sand.

Withdrawals of water from the '400-foot' and '600-foot' aquifers in the Baton Rouge industrial district have caused significant declines in the potentiome-tric levels. To evaluate the effect of future pump-age from the '400-foot' and '600-foot' aquifers, a digital model of these aquifers is being developed. The '400-foot,' '600-foot,' and adjacent aquifers and confining beds were mapped for developing the digital model. From top to bottom, the four layers mapped are: (1) the Mississippi River alluvi-al aquifer and the shallow Pleistocene deposits, (2) the '400-foot' aquifer, (3) the '600-foot' aquifer, and (4) the '800-foot aquifer. Maps were prepared on a 1:24,000 scale base map of the industrial area at Baton Rouge and on a 1:125,000 scale base map of part of the five-parish study area. For each of the Baton Rouge and on a 1:125,000 scale base map of part of the five-parish study area. For each of the four layers, the altitude of the base of the unit, net sand thickness, and thickness of the clay between that unit and the next deeper unit were determined and contoured. The '400-foot' aquifer has the most continuous sands, ranging from 25 to 400 feet in thickness. Both the '600-foot' aquifers have large areas where no sand was found in the stratigraphic interval of the two aquifers. Clays of the shallow Pleistocene deposits form the confining unit above the '400-foot' aquifer. The shallow Pleistocene sands are discontinuous sand lenses within the shallow Pleistocene deposits. The Mississippi River alluvial aquifer is a thick sand

and gravel aquifer (200 to 600 ft in thickn and graver adulter (200 to 600 ft in thickness) that is in hydraulic connection with the '400-ft' and '600-ft' aquifers beneath parts of the Mississippi River alluvial plain. Confining beds between aquifers range from 0 feet in thickness, where sands of two aquifers coalesce, to over 400 ft in thickness, where one or more aquifers contain no sand. ASSESSMENT OF HYDROGEOLOGIC CONDITIONS WITH EMPHASIS ON WATER QUALITY AND WASTEWATER INJECTION, SOUTHWEST SARASOTA AND WEST CHARLOTTE COUNTIES, FLORIDA.

Geological Survey, Tallahassee, FL. Water Resources Div.
C. B. Hutchinson

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Open File Report 90-709, 1991. 103p, 38 fig, 9 tab, 63 ref, append.

Descriptors: \*Florida, \*Geohydrology, \*Ground-water quality, \*Injection wells, \*Path of pollutants, \*Wastewater disposal, \*Water pollution sources, Aquifer systems, Aquifers, Groundwater move-ment, Mathematical models, Model studies, Perme-

The 250 sq mi area of southwest Sarasota and west Charlotte Counties is underlain by a complex geohydrologic system having diverse groundwater quality. The surficial and intermediate aquifer systems and the Upper Floridan aquifer of the Floridan aquifer systems contains its generate aquifering dan aquifer system contain six separate aquifers, or permeable zones, and have a total thickness of about 2,000 ft. Water in the clastic surficial aquifer about 2,000 ft. Water in the clastic surficial aquifer system is potable and is tapped by hundreds of shallow, low-yielding, supply wells. Water in the mixed clastic and carbonate intermediate aquifer system is potable in the upper part, but in the lower part, because of increasing salinity, it is used primarily for reverse osmosis desalinization feed water and irrigation. Potential groundwater contamination problems include flooding by storm tides unward movement of saline water toward. tides, upward movement of saline water toward pumping centers by natural and induced leakage or through improperly constructed and abandoned wells, and injected into deep zones. The study area encompasses seven wastewater injection sites that encompasses seven wastewater injection sites that have a projected capacity for injecting 29 million gallons per day (gpd) into the zone 1,100 to 2,050 ft below land surface. There are six additional sites within 20 miles. The numerical model was used to simulate injection through a representative well at a rate of 1 million gpd for 10 years. In this simulation, a convection cell developed around the injection well with the buoyant fresh injectant rising to form a lens within the injection your below the from a lens within the injection zone below the lower Suwannee-Ocala semiconfining unit. Around an ideal, fully penetrating well cased 50 ft into the injection zone and open from a depth of 1,150 ft to 2,050 ft, simulations show that the injectant moves upward to a depth of 940 ft, forms a lens about 600. If thick and correctly existing volume to the singulation should be supported to a depth of 940 ft, forms a lens about 600. upward to a depth of 940 ft, forms a lens about 600 ft thick and spreads radially outward to a distance of about 2,300 ft after 10 yrs. Comparison simulations of injection through wells with open depth intervals of 1,150 to 1,400 ft and 1,450 to 2,050 ft demonstrate that such changes in well construction have little effect on the area spread of the injectant lens or the rate of upward movement. tation, Finite difference methods, Groundwater resources. Hydraulic head

The groundwater hydrology and geochemistry of the Mesilla Basin in central-southern New Mexico and western Texas were studied as part of the Southwest Alluvial Basins Regional Aquifer-System Analysis program of the US Geological Survey. The Mesilla Basin, hydrologically repre-sentative of many alluvial basins, was studied by seniative of many anitym oasins, was studied by simulating the groundwater flow system using a digital model. Groundwater flow generally is away from the Mesilla Valley near Las Cruces and toward the valley in the southern part of the basin. A finite difference groundwater flow model of the senior to the student of the senior to the sen basin simulated groundwater flow to and from the Rio Grande and a series of drains that empties into the Rio Grande. The model also simulated evapo-transpiration from non-irrigated lands in the Me-silla Valley (about 2 acre-ft/acre) as a function of the difference between the altitude of the land surface and the model derived altitude of the water surface and the model derived antitude of the water table. Hydraulic conductivity of the uppermost layer generally was about 22 ft/day where the layer represented the Santa Fe Group, and about 60 ft/day where the layer represented the flood 60 ft/day where the layer represented the flood plain alluvium plus the upper part of the underlying Santa Fe Group. Hydraulic conductivity of other layers ranged from about 22 ft/day for the upper part of the Santa Fe Group to 3 ft/day for the lower part. Model derived hydraulic heads, drain discharge, and river depletions compared well with measured values except that model-derived hydraulic heads in the Las Cruces well field area were about 20 ft higher than measured hydraulic heads according to simulations for the desired hydraulic heads. According to draulic heads. According to simulations for the 1970's, about 80% of groundwater pumped for nunicipal, industrial, and domestic uses may have come from the Rio Grande, about 10% from salvaged evapotranspiration, and about 10% from aquifer storage. Drawdowns of 1 to 10 ft in 1975 caused by historical non-irrigation withdrawals may be measurable at distances of about 5 mi west of well fields at Las Cruces and Canutillo in or below the deep producing zones. The chemical composition of groundwater in the Mesilla Valley varies areally and vertically. Along the northwestern margin of the basin, sulfate and sodium are the ern margin of the ossin, suntare and sodium are the dominant ions in groundwater flowing into the basin, and the specific conductance of this water ranges from 1,400 to 2,310 microsiemens/cm at 25 C. USGS Open File Report 89-595, 1990. 38p, 8 fig, 4
tab, 10 ref. DOE Interagency Agreement DEAI08-78ET44802.

Descriptors: \*Franklin Lake Playa, \*Geohydro-logy, \*Groundwater resources, \*Hydrologic data collections, \*Soil water, \*Surface-groundwater re-lations, \*Unsaturated zone, California, Evapotranspiration, Hydraulic gradient, Meteorology, Pie-zometry, Vertical flow, Water level.

Hydrologic and other data are presented which were collected to further characterize the geohydrology and groundwater discharge at Franklin Lake playa, Inyo County, California. These data include: (1) hydrographs of water levels in piezometers; (2) vertical hydraulic gradients estimated from piezometer-nest data; (3) meteorological data from weather stations in the vicinity of Franklin Lake playa; and (4) estimates of moisture fluxes based on changes in soil moisture content in the unsaturated zone. Hydrographs of water levels in piezometers vary from being very smooth to having extreme fluctuations. Average water level altitudes from these hydrographs can be used to contour the water table altitude in the vicinity of Franklin Lake playa. Vertical hydraulic gradients estimated from piezometer-nest data can be used to estimate groundwater discharge, provided reliable

estimates of vertical hydraulic conductivity are available. Evapotranspiration estimates based on changes in soil moisture content in the unsaturated zone provide a basis of comparison for other methods such as the energy budget eddy correlation technique. (Lantz-PTT) W91-11089

ANALYSIS OF GROUND-WATER FLOW IN THE A-SAND AQUIFER AT PARAMARIBO, SURINAME, SOUTH AMERICA. Geological Survey, Tallahassee, FL. Water Resources Div.

A numerical aquifer simulation model was developed for a 619 sq km area to help understand the groundwater flow system and to aid in the management of pumpage from the A-Sand aquifer in Paramaribo, Suriname. Thirty years of continuous increases in pumpage from the A-Sand aquifer have created broad cones of depression in the aquifer's potentiometric surface that extend over hundreds of square kilometers. As a result of these water level declines, the aquifer is experiencing water level declines, the aquifer is experiencing problems of well field interference and salt water problems of well field interference and salt water encroachment. Aquifer tests had indicated a large variability in hydraulic conductivity; however, an acceptable calibration was achieved by using a uniform hydraulic conductivity of 90 m/day. Simulated transmissivity of the 2-m to 50-m thick aquifer wedge varies from 180 to 4,500 sq m/d between the southern and northern model boundaries. There simulations were made to demonstrate aries. Three simulations were made to demonstrate how the model can be used as a tool for water management. A transient simulation was made to management. A transient simulation was made to assess potentiometric surface changes resulting from pumpage during the period 1958 to 1987. Potentiometric surface maps for selected years show expanding and coalescing cones of depression as the number of well fields increased from one to six and pumping rates increased from 1,643 to 40,230 cu m/d. A hypothetical new well field, with a 6,000 cu m/d pumping rate, was simulated to demonstrate how additional pumping can lower the potentiometric surface at existing well fields. Another simulation redistributed pumpage by adding the above hypothetical new well field, but adding the above hypothetical new weil neit, du with an equivalent reduction in pumpage at the two most heavily pumped well fields, Zorg en Hoop and Livorno. Head gradients between Zorg en Hoop and the area where chloride concentratin through and the area where contorned concentrations in groundwater exceed 300 mg/L, were compared with 1987 gradients to show that redistributing pumpage might slow salt water encroachment and extend the useful life of the well field by 5 years. A particle tracking program was used to assess results of the flow simulations. The simulational content of the simulations assess results of the flow simulations. The simulated velocity averages about 133 m/yr within 4 km of the Livorno well field. Simulated velocities from the area of high chloride concentrations are highest toward the Leysweg and Zorg en Hoop well fields, indicating a high potential for increasing chloride concentrations in water from these well fields (I seek BTC). well fields. GEOHYDROLOGY AND WATER QUALITY OF KALAMAZOO COUNTY, MICHIGAN, 1986-

Geological Survey, Lansing, MI. Water Resources

Div. S. J. Rheaume.

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 90-4028, 1990. 102p, 21 fig, 36 tab, 3 plates, 30 ref,

Descriptors: \*Geohydrology, \*Groundwater quality, \*Kalamazoo County, \*Water quality, Calcium

bicarbonate, Chlorides, Groundwater recharge, Michigan, Nitrogen, Organic compounds, Pesti-cides, Sodium, Sulfates, Surface water.

Thick, glacial sand and gravel deposits provide most groundwater supplies in Kalamazoo County. Most industry, public supply, and irrigation wells completed at depths of 100 to 200 ft yield 1,000 gallons per minute (gpm) or more. Groundwater levels in Kalamazoo County, reflect short-term and long-term changes in precipitation and local pump age. Groundwater levels increase in the spring and age. Groundwater levels increase in the spring and decline in the fall. Recharge rates, for different geologic settings, were estimated from groundwater runoff to the streams. A county-wide average groundwater recharge rate is estimated to be 9.32 in/yr. Water of streams and rivers of Kalvana groundwater recharge rate is estimated to be 9.32 in/yr. Water of streams and rivers of Kalamazoo County is predominantly of the calcium bicarbonate type, although dissolved sulfate concentrations are slightly larger in streams in the southeastern and northwestern parts of the county. Concentrations of dissolved chloride in streams draining urban industrial areas are slightly larger than at other locations. Concentrations of total nitrogen and total phosphorus in streams are directly proportional to streamflow. Except for elevated concentrations of iron, none of the trace elements in streams exceeded maximum contaminant levels for streams exceeded maximum contaminant levels for drinking water established by the US EPA. Pesticides were detected in some streams. Groundwater in the surficial aquifers is of the calcium bicarbonate type, although sodium, sulfate, and chloride ions predominate at some locations. Concentrations of dissolved sodium and dissolved chloride in 6 wells were greater than most natural groundwaters in the State, indicating possible contamination from road salts. Water samples from 6 of the 46 wells sampled contained concentrations of total nitrate as nitrogen > 10.0 mg/L. Pesticides were detected in water from only one well. Water from drinking water established by the US EPA. Pestidetected in water from only one well. Water from five wells contained volatile organics. (Lantz-PTT) W91-11091

GEOPHYSICAL AND CHEMICAL INVESTI-GATIONS OF GROUND WATER AT FIVE IN-DUSTRIAL OR WASTE-DISPOSAL SITES IN LOGAN TOWNSHIP, GLOUCESTER COUNTY, NEW JERSEY, 1983-87.

GEOHYDROLOGY AND SIMULATION OF FLOW IN THE CHICOT AQUIFER SYSTEM OF SOUTHWESTERN LOUISIANA.

Geological Survey, Baton Rouge, LA. Water Resources Div.

D. J. Nyman, K. J. Halford, and A. Martin. State of Louisiana Water Resources Technical Report No. 50, 1990. 58p, 33 fig, 5 tab, 40 ref.

Descriptors: \*Chicot Aquifer, \*Geohydrology, \*Groundwater movement, \*Louisiana, \*Model studies, \*Simulation analysis, Aquifers, Groundwater mining, Lake Charles, Leakage, Water level.

Water was pumped at about 1 billion gallons per day (gpd) from the Chicot aquifer system in 1980 by industry and rice growers in southwestern Lou-isiana. Records indicate that water levels in wells declined, on average, as much as 1 ft/yr from 1900 to 1981 in the Lake Charles and rice growing areas. Water levels rose, on average, 2 ft/yr during the period 1982-85 because pumping rates during the period were reduced by 38% to 616 million gpd. The Chicot aquifer system consists of a com-plex series of alternating beds of unconsolidated plex series of anternating oceas of unconsonated sand, gravel, silt, and clay. A digital groundwater flow model was developed to simulate flow in the Chicot aquifer system and to estimate the effects of pumping. In general, model computed water levels compare closely with observed levels. Model recompare closely with observed levels. Model re-sults indicate that: (1) flow patterns in the Chicot aquifer system have been significantly altered downgradient from the area of outcrop since pre-development; (2) approximately a fourfold increase (from 259 to 1,113 million gpd) in flow through the system has occurred since major development began; (3) water levels in and near the pumping centers declined, on average. I flyr from pre-centers declined, on average. ters declined, on average, 1 ft/yr from pre

#### Groundwater-Group 2F

development to 1981; (4) under 1981 conditions, vertical leakage was the largest component of re-charge; and (5) water derived from aquifer storage is a relatively small part of flow in the entire system. The model is least sensitive to changes in system. The model is least sensitive to changes in a quifer storage and most sensitive to changes in the vertical conductance of the confining units. Simu-lations indicate that, disregarding the possibility of salt water encroachment in the aquifers along the coast, pumping rates 50% to 100% larger than the 1980 rate can be maintained indefinitely with the available recharge. AVAILABILITY OF GROUND WATER FROM UNCONSOLIDATED DEPOSITS IN THE MOHAWK RIVER BASIN, NEW YORK. Geological Survey, Albany, NY. Water Resources

Div. R. J. Reynolds.

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 88-4091, 1990. 9p, 10 maps, 175 ref.

Descriptors: \*Geohydrology, \*Groundwater movement, \*Groundwater resources, \*Maps, \*Mohawk River Basin, \*New York, \*Unconsoli-dated aquifers, Aquifer systems, Geology, Hydro-logic data collections, Well yield, Wells.

Information on the availability of groundwater from unconsolidated deposits has become increasingly important in water resource planning and management. State, county, and local agencies charged with providing adequate water supplies and safeguarding New York's groundwater quality need to know the location of unconsolidated aquifers that have the potential for water supply. To meet this need, the US Geological Survey, in cooperation with the New York State Department of Environmental Conservation, has undertaken an aquifer-mapping program in upstate New York to provide: (1) detailed geohydrologic mapping of selected aquifers that serve large population cen-ters at a scale of 1:24,000, and (2) reconnaissancetype geohydrologic information on each major river basin in New York at a scale of 1:125,000 or 1:250,000. This report shows the location of unconsolidated deposits with the Mohawk River basin at a:125,000 scale and gives the estimated potential yield of wells that are completed in these deposits. The basin is divided into three parts—east, south, and west-each of which is represented by three maps that show, respectively: (1) location, reported yield, diameter, and depth of wells that terminate in unconsolidated deposits; (2) surficial geology; and (3) estimated yields of wells that tap unconsolidated deposits. HYDROGEOLOGY OF THE VALLEY-FILL AQUIFER AT OWEGO, TIOGA COUNTY, NEW YORK.

Geological Survey, Albany, NY. Water Resources

Geological Survey, Albany, NY. water Resources Div. R. J. Reynolds, and J. D. Garry. Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 89-4000, 1990. 8p, 8 maps, 32 ref.

Descriptors: \*Aquifer systems, \*Geohydrology, \*Groundwater resources, \*Maps, \*New York, Geology, Hydrologic data collections, Land use, Owego, Permeability, Saturation, Water level, Water table, Well yield.

Most productive aquifers in upstate New York consist of unconsolidated deposits of glacial and alluvial sand and gravel that floor major river and stream valleys. Groundwater in these valley-fill aquifers can occur under either water table (unconfined) or artesian (confined) conditions. Farms, fined) or artesian (confined) conditions. Farms, industries, or municipalities overlie many of these aquifers because they typically form flat areas that are suitable for development, and generally provide an ample groundwater supply. This development, coupled with the generally high permeability of these deposits, and a typically shallow water depth to the water table, makes these aquifers

vulnerable to contamination from point sources such as landfills, road salt stockpiles, hydrocarbon fuel storage and other industrial facilities with a potential for contamination leakage, in addition to nonpoint sources such as urban and agricultural runoff and septic tank leachate. To facilitate water management decisions by State and local govern-ment agencies, the US Geological Survey, in coop-eration with the New York State Department of eration with the New York State Department of Health, began a study in 1980 to define the geohydrology of 18 extensively used unconsolidated aquifers in upstate New York. To date (1989) 15 of these aquifers have been studied and the results published as individual reports (at 1:24,000 scale). This set of maps summarizes the geohydrology of the valley fill aquifer system near Owego, in Tioga County, NY. The maps are based on geohydrologic data collected near Owego during this investigation and on data in US Geological Survey files and previously published Geological Survey reports. These data enabled the compilation of eight sheets: locations of wells and test holes (sheet 1), surficial geology (sheet 2), geologic sections (sheet surficial geology (sheet 2), geologic sections (sheet 3), water table altitude (sheet 4), saturated thickness of the valley-fill aquifer (sheet 5), estimated well yields (sheet 6), generalized soil permeability (sheet 7), and land use (sheet 8). HYDROLOGY OF THE FLORIDAN AQUIFER SYSTEM IN EAST-CENTRAL FLORIDA.

C. N. Tiboais. Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Professional Paper 1403-E, 1990. 98p, 78 fig, 8 tab, 213 ref, 3 app

Descriptors: \*Florida, \*Floridan Aquifer, \*Geohydrology, \*Groundwater movement, \*Groundwater Descriptors: Priorida, Priorida Aquifer, "Geohydrology, "Groundwater movement, "Groundwater resources, "Permeability, Aquifer systems, Aquifers, Dissolved solids, Groundwater discharge, Groundwater quality, Groundwater recharge, Mineralization, Simulation analysis, Transmission,"

The fresh groundwater flow system of east-central Florida consists of a thin surficial sand aquifer underlain by the thick, highly productive carbonate rocks of the Floridan aquifer system. On the basis of permeability, this system is divided into the Upper and Lower Floridan aquifers, which are separated by a less permeable limestone sequence referred to as the 'middle semiconfining unit.' The transmissivity of the Lower Floridan is less well known, but simulation suggests values in the range of 30,000 to 130,000 sq ft/day. Storage coefficients of both the Upper and Lower Floridan aquifers are about 0.001. Leakage coefficients of the confining bed that overlies the Upper Floridan range from 0.00001/4 to about 0.0006/d. The leakage coefficient of the middle semiconfining unit is about 0.00005/d. The chemical quality of the water in the Upper Floridan qualifer varies according to The fresh groundwater flow system of east-central 0.0005/d. The chemical quality of the water in the Upper Floridan aquifer varies according to proximity to recharge and discharge areas. Low concentrations of dissolved solids (< 250 mg/L) generally occur in recharge areas. However, in the discharge areas along the Atlantic Coast and along the St. Johns River, the dissolved solids concentration is generally > 1.000 mg/L, and in places exceeds 25,000 mg/L. The quality of water in the Lower Floridan is not well defined, but in east-central Florida, water in the Lower Floridan is probably more mineralized than water in the Upper Floridan. The hydraulics of the Floridan aquifer system under predevelopment conditions Upper Floridan. The hydraulics of the Floridan aquifer system under predevelopment conditions involve mostly recharge to the Upper Floridan (by way of leakage from the surficial aquifer), lateral movement through the Upper Floridan for short distances, and discharge by way of springs and seepage to streams. Relatively small amounts of discharge occur along the coast, and small amounts move into and out of the underlying Lower Flori-

dan. The imposition of pumping has altered the flow system, but not to a great degree. (Lantz-W91-11113

HYDROGEOLOGY OF THE POINT LOOK-OUT SANDSTONE IN THE SAN JUAN STRUC-TURAL BASIN, NEW MEXICO, COLORADO, ARIZONA, AND UTAH.

S. D. Craigg, W. L. Dam, J. M. Kernodle, C. R. Thorn, and G. W. Levings.

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Hydrologic Investigation Atlas HA-720-G, 1990. 2p, 12 fig, 33 ref.

Descriptors: \*Geohydrology, \*Groundwater quality, "Groundwater resources, "New Mexico, "Point Lookout Sandstone, "Regional Aquifer System Analysis, Aquifers, Arizona, Chlorides, Colorado, Dissolved solids, Drinking water, Fluorides, Groundwater discharge, Hydrogen ion concentration, Infiltration, Sandstones, Sulfates, Utah.

This report is one in a series resulting from the US Geological Survey's Regional Aquifer-System Analysis (RASA) study of the San Juan structural basin that began in October 1984. Summarized is information on the geology, occurrence and qual-ity of water in the Point Lookout Sandstone, one ity of water in the Point Lookout Sanastone, one of the primary water-bearing units in the regional aquifer system. The Point Lookout Sandstone is a source of water for domestic and livestock use in dilling denths and pumping levels are source of water for domestic and livestock use in areas where drilling depths and pumping levels are economically feasible and where water quality is acceptable. Water in the Point Lookout Sandstone occurs under both water table and artesian conditions. Potential recharge to the aquifer is from infiltration of precipitation and streamflow and from vertical leakage of water through confining beds. Reported transmissivity of the Point Lookout Sandstone ranges from 0.4 sq ft/d to 236 sq ft/d. A storage coefficient of 0.000041 was reported from drawdown in an observation well. The average hydraulic conductivity calculated from oil and gas hydraulic conductivity calculated from oil and g wells in the deeper parts of the basin is 0.0058 ft/d. The reported or measured discharge from 17 water Ine reported or measured discharge from I / water wells completed in the Point Lookout Sandstone ranges from 1 to 75 gallons per minute (gpm) and the median is 10 gpm/ft of drawdown and the median is 0.25 gpm/ft of drawdown. From a total of 37 samples for pH, 22 (59%) exceeded the standard. Out of a total of 43 samples for sulfate, 16 standard. Out of a total of 43 samples for suitrate, 10 samples (37%) exceeded the secondary drinking water standard. Only 1 sample for chloride out of 49 samples (2%) exceeded the standard. From 44 samples for fluoride, 9 samples (20%) exceeded the secondary drinking water standard of 4 mg/L. Twenty-nine samples (69%) from a total of 42 samples for dissolved solids concentration exceeded the secondary drinking water standard. No secondary drinking water standard. ed the secondary drinking water standard. No samples for nitrate exceeded the primary drinking water standard of 10 mg/L. (Lantz-PTT)

The Minnesota District of the U.S. Geological Survey's Water Resources Division is an earth-sciences agency whose job is to collect and interpret water resources data. During FY 1988, 56% of the District's program consisted of hydrologic studies and 44% hydrologic data collection. During this period, the District operated 145 well level stations; 79 daily streamflow stations, 93 high flow, partial record stations, 6 lake level stations; and 10 stage only stations. Water quality data were also collected at 5 sediment stations; 8 National Stream Quality Accounting Network stations; 2 Hydrologic Benchmark stations; and 6 miscellaneous water-quality stations. Four studies, which have been completed or are being worked on, are on agrichemicals in groundwater. These included the effects of agriculture, tillage, and rural residential development on water quality in surficial sandplain aquifers. The District also conducted 11 hydrologic Studies not directly related to agrichemicals in groundwater. These studies covered the major discipline ages of surface water, groundcals in groundwater. These studies covered the major discipline areas of surface water, groundwater, and water quality, as well as their interrela-tionships. (See also W91-11162) ( Rubinstein-PTT) W91-11167

GEOSTATISTICAL CHARACTERISTICS OF THE BORDEN AQUIFER.

Manitoba Univ., Winnipeg. Dept. of Geological

Engineering.
A. D. Woodbury, and E. A. Sudicky.
Water Resources Research WRERAQ, Vol. 27,
No. 4, p 533-546, April 1991. 10 fig, 8 tab, 45 ref,

Descriptors: \*Borden Aquifer, \*Data interpreta-tion, \*Geohydrology, \*Hydraulic conductivity, \*Path of pollutants, \*Plumes, \*Statistical analysis, \*Tracers, Groundwater pollution, Mathematical models, Ontario, Performance evaluation.

A field experiment for the geostatistical characterration of hydraulic conductivity and plume dispersion in the Borden aquifer, Ontario, was reexamined. The sampled data reveal that a number of outliers (low natural log (K) values) are present in the database. These low values cause difficulties in both variogram estimation and determining population statistics. The analysis shows that assuming either a normal distribution or an exponential dis-tribution for log conductivity is appropriate. The classical, Cressie/Hawkins, and squared median of the absolute deviation estimators were used to compute variograms. None of these estimators procompute variograms. None of these estimators provided completely satisfactory variograms for the Borden data except the classical estimator with outliers removed from the data set. Theoretical exponential variogram parameters were determined from nonlinear (NL) estimation. Differences were obtained between NL fits and those reported by Sudicky in 1986. For the classical-screened estimated variogram, NL fits reduces natural log estimated variogram. NL fits reduces natural log of Studies in 1760. For the classical-screening estimated variogram, NL fits produce a natural log (K) variance of 0.24, nugget of 0.07, and integral scales of 5.1 m horizontal and 0.21 m vertical along A-A'. For B-B' these values are 0.37, 0.11, 8.3, and 0.34. The fitted parameter set for B-B' data (horizontal and vertical) differed statistically from the

parameter set determined for A-A'. A probabalistic form of Dagan's equations relating geostatistical parameters to a tracer cloud's spreading moments also was evaluated using the parameter estimates and covariances determined from line A-A' as and covariances determined from the APA as input, with a velocity equal to 9.0 cm/day. The results were compared with actual values determined from the field test, but evaluated by the methods of both Freyberg and Rajaram and Gelhar. The geostatistical parameters developed produce an excellent fit to both sets of calculated plume moments when combined with Dagan's sto-chastic theory for predicting the spread of a tracer cloud. RESPONSE OF WATER LEVEL IN A WELL TO A TIME SERIES OF ATMOSPHERIC LOADING UNDER CONFINED CONDITIONS, Florida State Univ., Tallahassee. Dept. of Geolo-

D. J. Furbish. Water Resources Research WRERAQ, Vol. 27, No. 4, p 557-568, April 1991. 15 fig, 1 tab, 29 ref,

Descriptors: \*Atmospheric pressure, \*Confined aquifers, \*Geohydrology, \*Groundwater level, \*Groundwater movement, \*Mathematical models, \*Water level, \*Wells, Aquifers, Simulation, Storativity. Time series analysis.

The water level in a well that penetrates a confined aquifer can fluctuate in response to changes in atmospheric pressure. The response varies with the well casing and screen dimensions, the transmissi-vity, and compressibility of the aquifer, and to a small extent, its storativity. Recently this loading-pressure problem has been solved in terms of a pressure problem has been solved in terms of a frequency response function that characterizes how attenuation and phase shifts in the response signal vary with frequency. The counterpart of this solution in the time domain is an impulse response function. This solution has the immediate appeal that it can be used directly to filter raw loading and water level records via serial convolution, where the response at any time is a weighted aggregate of the previous loading signal. The im-pulse response function derives from well-known solutions to the slug test problem. When based on the Cooper-Bredehoeft-Papadopulos solution, the response function is precise but computationally intensive. Based on the Hvorsley solution, the reintensive. Based on the Hvorslev solution, the response function is computationally simple, but applicable only to aquifers with small storativity. Simulations and a field example clearly illustrate the dominating influence of transmissivity in dampening and lagging the response of a confined aquifer to a loading signal, and how both effects increase with higher frequency. The results also illustrate the weak influence of storativity in modulating the response signal. (Author's abstract) W91-11236

Descriptors: \*Drawdown, \*Pumping tests, \*Surface-groundwater relations, \*Wells, Aquifers, Errors, Groundwater budget, Hydraulic properties, Mathematical models, Model studies, Simula-

Analytical solutions for computing drawdowns and streamflow depletion rates often neglect conditions that exist in typical stream-aquifier systems. These conditions include: (1) partial penetration of the aquifer by a stream, (2) presence of a streambed clogging layer, (3) aquifer storage available to the pumping well from areas beyond the stream, and (4) hydraulic disconnection between the stream and the well. A methodology was devised for estimating extended flow lengths and other parameters used to approximate the increased head losses created by partially penetrating streams and clogging layer resistance effects. The computed stream depletion rates and drawdown distributions from several analytical solutions (Theis, Glover and several analytical solutions (Theis, Glover and Balmer, Jacob, Hantush) were compared to those obtained using a two-dimensional groundwater flow model. The stream geometry was approximated as a semicircle. Numerical simulation results indicate that, because of the use of simplifying assumptions, the analytical solutions can misrepreassumptions, the analytical solutions can misrepre-sent aquifer drawdown distributions and overesti-mate stream depletion rates. Assuming that a cor-rect simulation of the stream depletion phenome-non is provided by the numerical model, the error associated with each of the simplifying assumptions was determined. At a time of \$8.5 days after pump-tion became across in computed, stream depletion was determined. At a time of 3-8.3 days atter pumping began, errors in computed stream depletion rates due to neglect of partial penetration were 20%, those due to neglect of clogging layer resistance were 45%, and those due to neglect of storage areas beyond the stream were 21%. Neglecting hydraulic disconnection had only a minor effect (i.e., an error of 1% only at a time of 58.5 days after pumping began) on computed stream deple-tion rates and a noticeable effect on aquifer drawdown distributions. Generalized molecular hydrodynamics and irre-Generalized molecular hydrodynamics and irre-versible thermodynamics are used to derive the relation between a general wave vector and fre-quency-dependent diffusion tensor and the power spectral density. A non-local integrodifferential equation is the result. Among its physical implica-tions, the most important is that transport at a given point depends on all prior history of the transport process and on what is happening every-where else in space. This is in complete intuitive agreement with what would be excetted in fractal where eise in space. Insis in complete intuitive agreement with what would be expected in fractal porous media. The equation is a nonlocal extension of the classical Markovian equation for diffusion. An example of how the developed concepts can be applied in an isotropic fractal porous medium is presented. Descriptors: \*Aquifer characteristics, \*Aquifers, \*Geohydrology, \*Groundwater pollution, \*Groundwater quality, \*Nigeria, Boreholes, Conglomerate, Groundwater management, Lignite, Lithology, Rivers State, Saline water intrusion, Stratigraphy.

The Benin formation, formerly thought of as com-pletely continental in origin, contains brackish

water and marine deposits within its upper 0 to 300 meter section in places in Rivers State, Nigeria. The dominantly north to south flowing groundwater system, with excellent hydraulic characteristics, is abstracted from fluvial channel sands in the north and tidal channel, intertidal, and beach sands in the central and southern sectors of the state. The groundwater is contaminated in places by the leaching of pyritic lignites, iron stained/coated, clasts/grains, laterite clasts, and brackish water invasion from the creeks. Conglomerate and lignite beds, within the depth interval considered in this seas, winin the depth interval considered in this study, are more common in the northeast and eastern parts of the state. More borehole drilling in the area will generate more subsurface data that will be useful in improving the stratigraphic framework. (Author's abstract)

Thousands of wells have been dug in most French-speaking countries in West Africa to supply rural populations with potable underground water through village hydraulic programs. Many of these wells are located in endogenous granitogeneissic or slaty sandstonelike rocks that lie beneath 5-40 meters of weathered and decayed material. Most of these wells have a total depth of 40-70 meters, a daily discharge of about 10 cubic meters, and in-stantaneous discharges of 1-5 cu m/h. In spite of favorable hydrogeological and environmental con-ditions, many of these wells display high nitrate contents. A statistical approach on a regional scale was used to determine the cause of the high nitrate contents. It was determined that the source of contents. It was determined that the source of nitrates is linked mainly with localized deforestation by man. (Author's abstract) W91-11446

Descriptors: \*Tracers, \*Environmental tracers, \*Porous media, \*Heterogeneity, \*Groundwater movement, \*Data acquisition, Permeability, Porosity, Geohydrology, Statistical analysis.

Many current developments and utilizations of groundwater resources first require a study of their flow and transport properties. These properties are needed to evaluate possible changes in groundwater quality and the potential transport of hazardous solutes through the groundwater system. Investigation of transport properties of fractured rocks is an active area of research. Most of the current approaches to the study of flow and transport in fractured rocks cannot be easily used for analysis of tracer transport field data. A new approach is proposed based on a detailed study of transport

through a fracture of variable aperture-a twothrough a fracture of variable aperture—a two-dimensional strongly heterogeneous permeable system. It is suggested that tracer breathrough curves can be analyzed based on an aperture or permeability probability distribution function that characterizes the tracer flow through the fracture. The results can be extended to both a multi-fracture system and a strongly heterogeneous porous medium. Two major conclusions are: (1) Heterogemedium. Two major conclusions are: (1) Heterogeneity in fractures and also in porous media gives rise to flow channeling effects. Tracer transport through these flow channels can be characterized by a permeability probability distribution function. The mean of this distribution function is larger than that of the permeability probability function over the entire 2-D heterogeneous medium. Tracer concentration breakthrough curves can then be analyzed to obtain the parameters (mean and varianalyzed to obtain the parameters (mean and variance) of the permeability probability distribution function; and (2) Since this is a statistical approach to interpret tracer transport data, it is shown that it would be impossible to make accurate predictions would be impossible to make accurate predictions of tracer arrival concentrations at a point in time and space, due to local permeability variations. It is demonstrated that multiple-point or line/areal measurements of tracer transport should be made over a few spatial correlation lengths, that would average the variability and may yield dispersion parameter characteristic of the medium. In other words, this new approach may not be able to make point predictions of tracer transport, but may be able to predict tracer concentration over a region able to predict tracer concentration over a region of space. In many practical applications, perhaps this capability is all that is required. (Lantz-PTT) W91-11554

PIPING AND PSEUDOKARST IN DRYLANDS. G. G. Parker, and C. G. Higgins.

Geological Society of America Special Paper 252, 1990. p 101-110, 2 fig, 1 tab, 140 ref.

Descriptors: \*Piping, \*Pseudokarst, \*Groundwater movement, \*Erosion, \*Soil piping, \*Subsurface drainage, Soil water, Storm seepage, Arid lands, Gullies, Geohydrology, Storm runoff, Drainage.

Piping, a form of subsurface erosion that by several processes produces subterranean drainage conduits or tunnels in relatively insoluble materials, occurs widely in the Earth's drylands. It can affect hard, consolidated rock such as shale, claystone, and consonated rock such as snate, claystone, and siltstone, and even some sandstones and volcanic breccias. Silty sediments with 20% to 25% smectite clay and high exchangeable sodium content are especially susceptible to piping. Piping sites range from valley bottoms and stream terraces to uplands. Rainfall, snowmelt runoff, or irrigation water sinks into the ground or is diverted into water sinks into the ground or is diverted into water sinks into the ground or is diverted into surface openings, most commonly desiscation cracks. The water then seeps downward through the soil or follows vertical openings until it reaches an especially permeable layer or is blocked by an impermeable horizon. It seeps laterally downgradient toward an outlet in a surface drainage feature such as gully. Where the water emerges at the gully wall—sa a seep at first, later as a more concentrated flow-grains of sediment are entrained, thus initiating an incinient ripe. With the passage thus initiating an incipient pipe. With the passage of time and runoff events the tiny opening enof time and runoff events the tiny opening en-larges, extends headward upgradient, and finally grows so large that its roof caves in. This forms a new, small, ragged, lateral gully as a tributary to the parent gully. With time, more gullies form, and a large gully network develops. One result of such the parent guily, with time, more guilies form, and a large guily network develops. One result of such piping erosion is the development of landforms much like those of typical limestone karst terrains. Such landscapes are called pseudokarsts, and their features may include sinks, natural bridges, hanging dry valleys, disappearing streams, and subterranean drainage. Pseudokarst develops chiefly by subsurface grain-by-grain erosion of largely insoluble materials, whereas true karst is formed by molecule-by-molecule removal of dissolved ions from soluble rocks such as limestone, dolomite, and gypsum. Pseudokarst developed in soft valley fills may be altered radically by the effects of a single heavy rainstorm or snowmelt runoff. Gully heads have been known to retreat 10 m or more in such an event. However, pseudokarst developed in resistant rocks may last much longer. For instance, that near Round Rock, Arizona, has changed only

The Columbia Plateau in eastern Washington, north-central and northeastern Oregon, and western Idaho covers > 70,000 a mi underlain chiefly by basalt belonging to the Columbia River Basalt Group. The Plateau is a large structural basin whose deepest part lies near Pasco, Washington, where the total thickness of basalt may exceed 14,000 ft. The Columbia Plateau regional aquifer system is a major aquifer system that consists chiefly of a great thickness of basalt belonging to the Columbia River Basalt Group, of minor interbedded sedimentary materials, and of overlying undivided consolidated and unconsolidated sediments. ded sedimentary materials, and of overlying undi-vided consolidated and unconsolidated sediments. For hydrologic purposes, these rocks have been subdivided along stratigraphic boundaries into four geohydrologic units. These geohydrologic units are from oldest to youngest: the Grande Ronde, Wanapum, Saddle Mountains, and overburden units. Structure contour and thickness maps have been prepared for each unit and for selected sedi-mentary interbeds in this study. The Grande Ronde is the thickest most extensive geohydrolo-Ronde is the thickest most extensive geonydrolo-gic unit; each of the overlying younger units in turn cover less area and are less voluminous. Thicknesses of each unit range from a minimum of zero to a maximum of about 14,000 ft for the Grande Ronde, 1,200 ft for the Wanapum, and 800 ft for the Saddle Mountain geohydrologic unit. The maximum thicknesses for each of the geohy-The maximum thicknesses for each of the geony-drologic units occur near the deepest part of the structural basin near Pasco, Washington. The thickest overburden, 2,000 ft, occurs in the Grande Ronde Valley near La Grande, Oregon, but is generally much thinner elsewhere. This report contains ten separate sheets. Each sheet describes in greater detail that part of the geologic framework that it represents: geologic map (sheet b). work that it represents: geologic map (sheet 1); structural features (sheet 2); altitude of top of Grande Ronde Basalt and thickness of Grande Ronde geohydrologic unit (sheet 3); thickness of Wanapum-Grande Ronde interbed (sheet 4); thick-Wanapum-Grande Ronde interbed (sheet 4); thickness of Wanapum geohydrologic unit (sheet 5); altitude of top of Wanapum Basalt (sheet 6); thickness of Saddle Mountains-Wanapum interbed (sheet 7); thickness of Saddle Mountains geohydrologic unit (sheet 8); altitude of top of Saddle Mountains Basalt (sheet 9); and thickness of overburden (sheet 10). HYDROGEOLOGY, WATER QUALITY, AND GROUND-WATER DEVELOPMENT ALTER-NATIVES IN THE LOWER WOOD RIVER GROUND-WATER RESERVOIR, RHODE ISLAND.

Geological Survey, Providence, RI. Water Resources Div.

D. C. Dickerman, E. C. Todd Trench, and J. P.

Russen.
Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 89-4031, 1990. 109p, 30 fig. 15 tab, 59 ref.

Descriptors: \*Geohydrology, \*Groundwater management, \*Groundwater quality, \*Rhode Island, \*Water resources development, \*Wood River Basin, Dissolved solids, Finite difference methods, Groundwater resources, Hydraulic head, Model studies, Nitrates, Pesticides, Well yield.

The 36 sq mi lower Wood River study area is located within the Pawcatuck River basin in southern Rhode Island. Stratified drift is the only princiern Rhode Island. Stratified drift is the only principal geologic unit capable of producing yields > 350 gallons per minute (gpm). The stratified drift aquifer consists of interbedded lenses of sand and gravel, with lesser amounts of silt, silty sand, and clay. Transmissivity of the aquifer ranges from 8,600 to 36,400 sq h/d. Water table conditions prevail in the aquifer, which is in good hydraulic connection with perennial streams and ponds. The chemical quality of groundwater in the study area is generally good to excellent and suitable for most uses. The water is soft, slightly acidic, and typically contains < 100 mg/L dissolved solids. Locally, however, groundwater has been contaminated with nitrate, pesticides, and radionuclides associated with various land use and waste disposal activities. Concentrations of Fe and Mn locally exceed Federal drinking water standards, but probably are derived from natural sources. A digital finite difference model of the groundwater flow system was ference model of the groundwater flow system was used to simulate the interaction between surface water and groundwater. Differences between computed model heads and measured heads in 33 observation wells were < 1.80 ft at 80% of the observation well-nodes. Total pumpage for selected development alternative simulations ranged from 6.0 to 11.0 mgd (million gallons per day). from 6.0 to 11.0 mgd (million gallons per day). Individual wells were pumped at constant rates of 1.0 mgd for all simulations. The areas most favorable for development of high capacity wells (350 gpm or more) are along the Wood River, Meadow Brook, Meadow Brook Pond, and the area around Ellis Flats. Thirty-six to 43% of the water withdrawn from wells will be derived from induced recharge from surface water sources. Development alternatives simulated in this study indicate that the alternatives simulated in this study indicate that the groundwater reservoir can sustain withdrawals of 6 to 9 mgd under long-term average annual hydrological conditions, without causing excessive streamflow depletion or decrease in aquifer saturated thickness. However, it may be necessary to reduce pumpage below 6.0 mgd to maintain some flow in Meadow Brook during drought periods. (Author's abstract) (Author's abstract) W91-11572

HYDROLOGY OF THE ARBUCKLE MOUNTAINS AREA, SOUTH-CENTRAL OKLAHO-

MA. Geological Survey, Oklahoma City, OK. R. W. Fairchild, R. L. Hanson, and R. E. Davis. Oklahoma Geological Survey Circular 91, 1990. 112p, 29 fig, 20 tab, 42 ref, 8 append, 2 plates.

Descriptors: \*Arbuckle Mountains, \*Geohydro-logy, \*Groundwater resources, \*Karst, \*Oklaho-ma, Aquifers, Dissolved solids, Groundwater movement, Groundwater quality, Groundwater re-charge, Hydrologic budget, Surface-groundwater relations, Water level, Water quality.

Rocks that make up the Arbuckle-Simpson aquifer crop out over 500 sq mi in the Arbuckle Mountains province in south-central Oklahoma. The aquifer consists of limestone, dolomite, and sandstone of consists of limestone, dolomite, and sanostone of the Arbuckle and Simpson Groups of Lake Cam-brian to Middle Ordovician age and is 5,000-9,000 ft thick. The rocks were subjected to intensive folding and faulting associated with major uplift of the area during Early to Late Pennsylvanian time. the area during Early to Late remsylvaman time. Water in the aquifer is confined in some parts of the area, while in other parts it is unconfined. The average saturated thickness of the aquifer is 3,500 ft in the outcrop area. Water levels measured in

wells fluctuated from 8-53 ft each year, primarily in response to recharge from rainfall. Recharge to the aquifer is estimated at 4.7 in/yr. The average storage coefficient of the aquifer is estimated at 0.008, and the average transmissivity is estimated at 15,000 sq. ft/day. Based on an average saturated thickness of 3,500 ft and a storage coefficient of 0.008 the values of groundwater contained in the thickness of 3,500 it and a storage outcome.

0.008, the volume of groundwater contained in the

500 sq mi outcrop area is 9 million acre-ft. An

undetermined amount of fresh water probably

exists in the aquifer around the periphery of the aquifer outcrop. Base flow of streams that drain the aquifer accounts for 60% of the total annual the aquirer accounts for over of the total annual runoff from the outcrop area and is maintained by numerous springs. The close hydraulic connection between streams in the outcrop area and the aquirer is shown by a close correlation between base flow in Blue River and the fluctuation of ground-water leavels in the walls in the Blue River basin water levels in five wells in the Blue River basin. This correlation also exists between the discharge Inis correlation asso exists seleween the uschange by Byrds Mill Spring and the fluctuation in water level in a nearby observation well; increase and decrease in spring discharge correspond to a rise and fall of the water level in the well. The chemical quality of water from the Arbuckle-Simpson coulfer is withhele for most industrial and municipal. aquifer is suitable for most industrial and municipal uses. The water is hard and of the bicarbonate type; the average hardness is 340 mg/L, and the average dissolved solids concentration is 360 mg/ L. (Author's abstract) W91-11590

EVALUATION OF SITE-SELECTION CRITE-EVALUATION OF SITE-SELECTION CRITE-RIA, WELL DESIGN, MONITORING TECH-NIQUES, AND COST ANALYSIS FOR A GROUND-WATER SUPPLY IN PIEDMONT CRYSTALLINE ROCKS, NORTH CAROLINA. C. C. Daniel.

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water Supply Paper 2341, 1990. 35p, 22 fig, 3 tab. 21 ref.

Descriptors: \*Cost-benefit analysis, \*Groundwater management, \*Groundwater quality, \*Groundwater resources, \*Monitoring, \*North Carolina, \*Pieder resources, 'Monitoring, 'North Carolina, 'Pret-mont Physiographic Province, 'Wells, Crystalline rocks, Economic aspects, Geohydrology, Model studies, Site selection, Statistics, Well yield.

A statistical analysis of data from wells drilled into A statistical analysis of data from well stitled into the crystalline rocks of the Piedmont and Blue Ridge provinces of North Carolina verified and refined previously proposed criteria for the siting of wells to obtain greater than average yields. An opportunity to test the criteria was provided by the expansion of the town of Cary's municipal ground-water system. Three criteria were used: (1) type of rock; (2) thickness of saturated regolith based upon topography; and (3) presence of fracture and joints topography; and of presence of nacture and Johns based upon drainage lineation. A conceptual model of the local geohydrologic system was developed to guide the selection of the most favorable well sites, and on the basis of the model, six type sites were determined. Eleven of the twelve test that were located on the basis of type sites yielded from slightly above average to as much as six times the average yield to be expected from particular rock types as reported in the literature. Only one well drilled at a type site had a less than average yield. One well not located at any of the type sites produced little water. Long-term testing and moniproduced little water. Long-term testing and mon-toring after the wells were put into production showed that an 18-hour-on, 6-hour-off pumping cycle was much more effective in terms of total production, reduced head loss, and less drawdown, then a 5-day-on and 2-day-off cycle. It was also observed that long-term yields by the production wells were about 75% of those predicted on the basis of 24-hour pumping tests and only about 60% of the driller's reported yields. Cost analysis abouted that he write criterio selected wall effect. showed that by using criteria selected well sites, a cost-effective well system can be developed that cost-effective well system can be developed that will provide water at an equivalent or lower cost than a surface water supply. The analysis showed that the system would be cost-effective if only one high yield well were obtained out of every four drilled. (Author's abstract)

Digital cross-section models, hydrograph separa-tion, and other analytical methods were used to describe groundwater flow and stream-aquifer redescribe groundwater flow and stream-aquiter re-lations for the clastic Coastal Plain aquifers of eastern Alabama, Georgia, and western South Carolina. Cross-section model simulations indicate that the spatial distribution of net recharge and discharge is highly variable and ranges from < 1.0 to about 20 inches/year. The water table configuto about 20 inches/year. The water table configu-ration largely determines the distribution of hy-draulic potential in cross-section at least to the top of the uppermost regional confining unit. Simulat-ed discharge to the largest rivers ranges from 7% to 17% of total net recharge, and represents flow along the longest flowpaths of a cross section. A hydrologic budget indicates that total mean annual aquifer recharge equals about 9,000 cu ft/sec. Of this quantity, 780 cu ft/sec is discharged from the regional flow regime to regional drains. 1,950 cu regional flow regime to regional drains, 1,950 cu ft/sec is discharged from the intermediate flow It/sec is discharged from the intermediate flow regime to streams tributary to regional drains near the point of recharge. Evapotranspiration occurs at a rate of 660 cu ft/sec. A subsurface flow of 310 cu ft/sec occurs downgradient from the study area and represents that component of recharge not discharged to any stream. (Author's abstract) W91-11598

A model of water and solute transport in macro-porous soils has been evaluated in column break-through experiments under field conditions. Hydraulic properties were first measured in replicate

soil monolith lysimeters sampled from grass pas-ture and continuous barley treatments in a clay soil. A pulse input of 0.05 M KCl was then sup-plied by drip irrigation and measurements made of the water discharge and chloride leaching resulting from the natural rainfall over a 1-month period. The results showed that the macropores constituted the dominant flow pathway (accounting for 80% of the total water outflow) and that diffusive exchange of chloride between the two flow do-mains was the main factor causing variability in leaching. Larger hydraulic conductivities and ma-croporosities in the lower topsoil and at plow depth in the grass pasture monoliths were taken as evidence of structural amelioration. Less of the applied chloride was leached in the grass mono-liths than in the barley (means of 20% and 31%, respectively). This was mostly due to a smaller effective aggregate size and thus a more efficient diffusion-controlled retention. (Author's abstract) (See also W91-10803)

Descriptors: \*Erosion, \*Frozen soils, \*Infiltration, \*Runoff, \*Sagebrush, \*Soil erosion, \*Soil water, Infiltration capacity, Plant cover, Range grasses, Soil temperature, Statistical analysis, Vegetation

Soil infiltration capacity and interrill erosion are significantly influenced by soil frost on western rangelands which are characterized by cold win-ters and numerous freeze-thaw cycles. However, little is known about the variable influence of this phenomenon. Infiltration and interrill erosion were measured within a sagebrush-grass plant community during the winter, spring, and summer of 1989. Significant spatial and temporal differences in infiltration capacity were found for shrub coppice dune and dune interspace soils. Infiltration was generally higher for coppice dune soils compared to interspace soils throughout the year. Infiltration capacity for both soils was lowest early in the year when the soil was frozen or saturated, then increased as the soil dried in the spring and summer. Interrill erosion was consistently lower for coppice dune soils compared to interspace soils. Erosion dulie solis compared to interspace soils. Existing from interspace soils was greatest during a 19-day period in late winter characterized by diurnal freeze-thaw cycles, saturated surface soil conditions, and soil slaking. Estimates of unsaturated flow often require an assessment of the relationship between unsaturated hydraulic conductivity (Ku) and moisture content. ured Ku-moisture relationships for a well-Measured Ku-moisture relationships for a wein-sorted sandy soil were obtained using the instanta-neous profile method during snowmelt recharge. These values were compared with estimates from three approaches: the Campbell equation, a modi-fied version of the Campbell model that considers residual water, and the rate of isotopic tracer dis-placement during infiltration. The modified Camp-bell model provided the best fit to the observed although all three methods over-predicted Ku. The isotopic tracer method overestimated observed Ku values by 2.6-4.5 times. This may reflect served Ku values by 2.6-4.3 times. This may reflect the role of macropores upon hydraulic conductivities during infiltration, since the tracer method is employed during recharge, while the instantaneous profile method is generally used during drainage periods when macropores are nonconductive. Whereas Ku estimates derived from empirical approaches such as the Campbell model may be valid during conditions of drainage, the isotopic tracer ourning conditions of dramage, the isotopic tracer model appears to provide more realistic conductiv-ity values during infiltration. The isotopic tracer method also provides a direct means of estimating the immobile fraction of total soil water. (Author's abstract) W91-10904

SOIL WATER DYNAMICS RELATED TO WATERLOGGING IN A SLOPING CATCHMENT. Eastern Univ., Chenkaladi (Sri Lanka). Div. of Agricultural Engineering.
C. S. Atputhanathan, E. R. N. Gunawardena, and K. R. Rushton.

Journal of Hydrology JHYDA7, Vol. 123, No. 3/ 4, p 279-295, March 1991. 9 fig, 1 tab, 22 ref.

Descriptors: \*Slopes, \*Soil water, \*Waterlogging, \*Watersheds, Drainage, Flow, Flow pattern, Hy-draulic conductivity, Hydrologic budget, Irriga-tion, Mathematical models, Model studies, Water

A study to understand the factors contributing to waterlogging was conducted in a small catchment of 5.4 ha in an irrigation scheme in the Eastern Dry Zone of Sri Lanka. Extensive mean of groundwater heads, soil moisture profiles and other hydraulic properties were made with special emphasis on the waterlogged areas. An understanding of the importance of the lateral movement of water has been developed using a mathematical model which represents both lateral and vertical components of flow. The study demonstrated that standard techniques, such as an overall catchment water balance and SEW index (the index is the sum of excess water table elevations about a 30-cm or excess water table elevations about a 30-cm depth and expressed as cm-days), do not provide an adequate explanation of waterlogging in sloping lands with surface irregularities. The field results show that the waterlogging problem is spatially distributed, hence the averaging of parameters does not explain the observed results. The discrete space-discrete time finite difference model devel-oped for this study has successfully represented the oped for this study has successfully represented the complex nature of waterlogging and rapid drying. Important features include: variations in hydraulic conductivity with depth; variations in hydraulic conductivity along the profile; the limited distance affected by the drain; and the ponding of water on the soil surface. The agreement between the simulated and field results was satisfactory. (Agostine-PTT) PTT W91-10906

SELF-AFFINE SCALING AND SUBSURFACE RESPONSE TO SNOWMELT IN STEEP TER-

Pennsylvania State Univ., University Park. Dept. of Civil Engineering.
C. J. Duffy, K. R. Cooley, N. Mock, and D. H.

Journal of Hydrology JHYDA7, Vol. 123, No. 3/ 4, p 395-414, March 1991. 15 fig, 23 ref. USDA Agricultural Research Service Cooperative Agreement 58-0401-7-00145.

Descriptors: \*Groundwater movement, \*Mathematical studies, \*Model studies, \*Runoff, \*Slopes, \*Snowmelt, \*Subsurface water, \*Sufface-groundwater relations, Base flow, Bedrock, Dynamics, Flow, Hysteresis, Permeability, Streams, Topogra-Watersbeds

The use of local scaling transformations is proposed as a framework for modeling the geometry and dynamic response of subsurface flow from steep hillslopes. The study site is the Upper Sheep Creek Watershed, a first-order sub-basin in the Reynolds Creek Experimental Watershed, southest Idaho. The purpose of the study was to gain insight into the evolution of snowmelt, subsurface flow, and runoff generation in this rugged volcanic terrain. In this phase of the study rescaling geometrically proportional (self-affine) surface and bedrock slope profiles provides an analytical framerically proportional (self-affine) surface and bed-rock slope profiles provides an analytical frame-work for defining the shape, volume and dynamic changes of saturated flow for this hillslope system. Rescaling self-affine hillslope trajectories along a stream reach, collapses the flow-domain to a unit cube. A dynamic model for hillslope runoff is proposed, and implications for modeling topo-craphic controls on the snowmelt process are sucgraphic controls on the snowmelt process are significant gested. An experimental relation between volu of water stored on the hillslope and baseflow from the stream reach, is shown to exhibit hysteretic behavior. The hysteresis is interpreted as resulting from heterogeneities of the hillslope permeability, and transient subsurface storage in the near-chan-nel region. (Author's abstract) W91-10912

CAUSES OF DEGRADATION OF CHEMICAL AND PHYSICAL PROPERTIES OF CHERNOZEMS IRRIGATED WITH NONMINERA-LIZED WATER.

Moscow State Univ. (USSR). Dept. of Soil Sci-

ence. F. R. Zaydelman, and I. Y. Davydova. Soviet Soil Science SSSCAE, Vol. 22, No. 4, p 11-19, 1990. 8 tab, 11 ref. Translated from Pochvovedeniye, No. 11, p 101-108, 1989.

Descriptors: \*Chemical properties, \*Irrigation effects, \*Physical properties, \*Soil properties, \*Soil ypes, Chernozems, Lysimeters, Soil compaction, Soil organic matter, Waterlogging.

A study was made of the effect of irrigation on the properties of the solid phase of an A-plow horizon of Typical Chernozem and on the composition of lysimeter waters using nonmineralized water at rates not exceeding the field capacity and causing short-term (5 hour) and prolonged (2 month) waterlogging. Short-term over-irrigation with fresh water in the presence of fermentable organic matter causes rapid degradation of these soils and their compaction. The cause of this phenomenon is their compaction. The cause of this phenomenon is due to the development of gleying under a periodically stagnant regime. It is accompanied by a sharp decrease in the redox potential of soils and their acidification, discharge into lysimeter waters of large amounts of iron and calcium, increase in humus mobility, narrowing of the C-HA/C-FA ratio and by a sharp decrease in permeability (by 1-2 orders of magnitude). Gley formation in Chernozems is the cause of their degradation where fresh water is to be used for irrigation. The major problem in the irrigation of Chernozems lies in the selection of measures which will preclude the desection of measures which will preclude the deselection of measures which will preclude the de-velopment of this soil-forming process. Agriculture, Volgograd (USSR).
T. A. Kretinina.

T. A. Kretinina. Soviet Soil Science SSSCAE, Vol. 22, No. 4, p 50-58, 1990. 4 tab, 19 ref. Translated from Pochvove-deniye, No. 9, p 44-51, 1989.

Descriptors: \*Agriculture, \*Chestnut soils, \*Fertil-izers, \*Irrigation effects, \*Physical properties, \*Soil types, Aeration, Aggregates, Calcareous soils, Clays, Dispersion coefficient, Nitrogen, Porosity.

The effect of long-term (12-year) fertilization of irrigated soil on its physical properties was studied. Studies were carried out in the arid zone of the Lower Volga region in an experimental six-field fodder-grain crop rotation. The soil of the experimental plot is a strongly calcareous Light-Chestnut clay loam. It was found that Light-Chestnut soil becomes finer textured under irrigation. The concept of clay in the above layer irregated by 7, 106. tent of clay in the plow layer increased by 7-10% during two crop rotations. A variable degree of during two crop rotations. A variable degree of fertilization had no effect on particle-size composition. Long-term application of increasing amounts of nitrogen fertilizers against a P60K60 background resulted, compared to the control, in an increase in the bulk density of the soil and in a decrease of its total porosity and aeration porosity, rate of CO2 liberation from the soil surface as well as of the content and water stability of agronomi-cally valuable aggregates. The dispersion coeffi-cient increased and the structure factor decreased. cient increased and the structure factor decreased. With application of average and large amounts of nitrogen fertilizers alone and in combination with manure, the unfavorable changes in the agrophysical properties of a Light-Chestnut soil are less pronounced. PHYSICAL PROPERTIES OF IRRIGATED CHERNOZEMS OF THE SOUTHERN UKRAINE. Odesskii Gosudarstvennyi Univ. (USSR).

S. P. Poznyak. Soviet Soil Science SSSCAE, Vol. 22, No. 4, p 67-74, 1990. 4 tab, 12 ref. Translated from Pochvove-deniye, No. 2, p 48-55, 1990.

Descriptors: \*Irrigation effects, \*Physical properties, \*Soil properties, \*Soil types, \*Ukraine, Aeration, Aggregates, Chernozems, Density, Particle size, Percolation, Porosity, Saline water, Soil profiles, Soil water, Sprinkler irrigation.

To investigate the changes in the physical condi-tions of Chernozems under irrigation, several phys-ical properties of Ukrainian soils in the Ingulets. Lower Dniester, and Tatarbunar (terrace plain and drainage divide plateau) irrigation systems, where low salinity waters are used, were studied. In the study region irrigation is performed by sprinkling, using DDA-100M equipment. The changes in physical properties within the above irrigation sys-tems were assessed by comparing the results of investigations made in 1971 on non-irrigated and irrigated soils with results obtained on irrigated soils in 1986. To elucidate the contribution of irrigation to changes in the physical properties of low salinity waters are used, were studied. In the irrigation to changes in the physical properties of Chernozems, a comparison was made between the particle-size and microaggregate composition, the density of the soil and its solid phase, its bulk density of the soil and its sond phase, its bulk density, the total porosity and aeration porosity, and water uptake and percolation. It was found that irrigation of Chernozems with low-salinity waters in the Ingulets, Lower Dniester and Tatarbunar systems degrades their physical, hydro-physical, and air-water properties and results in argillization and compaction. The direction, character, rate, and depth of these processes in the soil profile depend on the length of irrigation. (Agostine-PTT) W91-10915

SORPTION PROPERTIES AND MOISTURE HYSTERESIS OF SOILS.

Akademiya Nauk SSSR, Novosibirsk. Inst. of Soil Science and Agrochemistry. N. I. Chashchina.

Soviet Soil Science SSSCAE, Vol. 22, No. 4, p 87-95, 1990. 2 fig, 1 tab, 15 ref. Translated from Pochvovedeniye, No. 2, p 89-96, 1990.

Descriptors: \*Hysteresis, \*Physical properties, \*Soil properties, \*Soil water, \*Sorption, Adsorption, Chernozems, Chestnut soils, Desorption, Porosity, Soil types.

The sorption characteristics and thermodynamics of soil moisture in Chernozems and Chestnut Brown soils of the southern zone of West Siberia were studied, and the boundary between strongly and loosely bound water was identified. The water adsorption and desorption isotherms of Siberian soils were obtained by studying the energy equilibrium of the soil solution with the potential of the surrounding system, i.e., by the hydroscopic technique. To investigate hysteresis, the measurements were made both during removal of water from the soil sample and during addition of water to it. The data on six Siberian soils indicate that almost no moisture hysteresis occurs in the light loam and loamy sand soils. In addition, hysteresis is not always directly dependent on the specific surface area of the soil. It may be assumed that major factors in the occurrence of hysteresis are the surface quality of the soil particles (form, depth, and width of depressions on them) and the porosity of the soil, i.e., the factors that give rise to capil-lary condensation. This is also indicated by the fact that in most of the Siberian soils that were studied hysteresis began to appear only when the relative humidity of the air exceeded 0.352. (Agostine-W91-10916

SECONDARY SALINIZATION OF SOILS OF THE DNIESTER DELTA FLOODPLAIN.

Kiev State Univ. (USSR). Dept. of Geography. M. R. P. Fedorishchak, V. V. Tsar, and P. G. Shishchenko.

Soviet Soil Science SSSCAE, Vol. 22, No. 4, p 101-112, 1990. 1 fig, 4 tab, 15 ref. Translated from Pochvovedeniye, No. 9, p 86-96, 1989.

Descriptors: \*Deltas, \*Flood control, \*Flood Descriptors: "Detais, "Flood Control, "Flood rolling, "Flood Control, "Flood C

An increase in salinity of water as a consequence An increase in saimly of water as a consequence of reduced runoff is currently taking place in the Dnestrovskiy liman and estuary of the Dniester. A study of the salinization of Delta-Floodplain soils was conducted. The study included particle-size analysis of Delta-Floodplain soils, salinity measurements of the Dnestrovskiy liman, analysis of salt composition of soils and groundwater of the estua-rine portion of the floodplain and of the coasts of the Dnestrovskiy liman. It was found that intrusion of Black Sea waters into the Dnestrovskiy liman increased as a result of regulation of flow of the Dniester and progressive consumptive use of its waters by various branches of the national economy. This led to an increase in salinity not only of liman waters but also of groundwater of coastal areas, including the estuarine portion of the river valley. Under dry climate conditions in the steppe vaney. Oldet my Chinace conditions in the steppe zone an increase in mineralization of groundwater close to the surface leads to secondary salinization of Delta-Floodplain soils. Also contributing to an accumulation of salts in soils is the shorter duration of high water flows and floods, which significantly reduces their role in natural desalinization of soils. Secondary salinization of soils differs in various parts of the delta floodplain. The content of chlorine and sodium increases from the apex to the lower part of the delta. Highest salt accumulations occur predominantly in upper layers of the soils, which attests to the progressive character of the salinization. (Agostine-PTT) W91-10917

Geotechnical engineers throughout the world are familiar with the challenges posed by expansive soils; vertical ground movements associated with expansive soil deposits cause more damage to light engineered structures than all other natural disasters combined. A numerical model was developed to salvie matric suction changes and vertical ters comoined. A numerical model was developed to relate matric suction changes and vertical ground movements. The research considers one-dimensional vertical ground movements under open-vegetated fields subject to changing climatic conditions. A percentage of the Thornthwaite potential evapotranspiration model proved to be adequate to characterize the surface flux boundary quate to characterize the surface flux boundary condition. The infiltration and exfiltration processes were modeled separately for the field conditions. During infiltration, shrinkage cracks and the macrostructure of the soils dominate behavior. During this process, bulk permeabilities in the order of 0.000001 to 0.0000001 m's were required to simulate measured ground movements. Exfiltration processes are dominated by flow in the vapor phase as drying occurs in the soil. Bulk permeabilities in the order of 0.000000001 to 0.00000000001 m/s were required to simulate the measured m/s were required to simulate the measured ground movement. The simulations of ground movements would also indicate that thermally induced suctions (i.e. winter freezing conditions) could account for a significant portion of the seasonal vertical ground movements. The numerical model can also be used to predict seasonal ground movements beneath light engineered structures. Further research, however, is required to better understand how to establish the surface flux boundary condition. There is also a need for more case histories to enlarge the database of unsaturat-ed soil parameters. (Author's abstract) W91-10945

The processes, flow paths, and residence times associated with subsurface flow are critically important in the interpretation of hydrochemical re-

sponses in steep, forested, upland catchments in humid temperate climates, where subsurface flow contributes a large portion of stormflow, as well as base flow, occurring in streams. A 3-m wide by 9-m long by 1-m deep soil block on a forested hillslope near Orono, Maine, was isolated by excavation of encircling trenches. A sprinkler system for application of water and potassium bromide tracer was constructed over the pick. Outflow was for application of water and potassium bromine tracer was constructed over the plot. Outflow was collected at six locations with troughs. Experi-ments were conducted at application rates of 2.5, 5, and 10 cm/h. Pulses of tracer were applied subse-quent to attainment of steady flow and breakand 10 cm/h. ruises of tracer were applied succeptured to attainment of steady flow and breakthrough curves were measured at all outflow points. Recession limbs of outflow hydrographs exhibited distinct breaks when plotted on semilogarithmic axes, indicating drainage from at least two distinguishable pore size classes or flow pathways. Solute breakthrough curves were dominated by a single peak; travel times of solute were inversely related to the application rate. A secondary peak in the outflow curve, which is consistent with transport theories for a homogeneous soil, was observed in all cases. This second peak is unexalained, but is conceptually consistent with the observed in all cases. Inis second peak is unex-plained, but is conceptually consistent with the notion of transport in at least two pore size classes. An undisturbed soil core (diameter of 30 cm and length of 40 cm) was sprinkled at the same rates as was the soil block, using Methylene Blue as tracer in the last run. Drainage hydrographs and visual examination of dye stains in the block indicated examination or dye stains in the block indicated also at this smaller scale that flow and transport are controlled by preferred paths in the soil, paths that cannot be morphologically distinguished from the surrounding soil matrix. Theoretical explanations of processes on such hillslopes need to account for this fact. (Author's abstract)

IMPROVED ANALYSIS OF GRAVITY DRAINAGE EXPERIMENTS FOR ESTIMATING UNSATURATED SOIL HYDRAULIC FUNCTIONS. J. B. Sisson, and M. T. van Genuchten. Water Resources Research WRERAQ, Vol. 27, No. 4, p 569-575, April 1991. 3 fig, 2 tab, 26 ref.

Descriptors: \*Gravity drainage, \*Hydraulic conductivity, \*Soil water, \*Unsaturated flow, Data processing, Differencing, Drainage, Infiltration, Performance evaluation.

Unsaturated hydraulic properties are important parameters in any quantitative description of water and solute transport in partially saturated soils. Most in situ methods for estimating the unsaturated hydraulic conductivity (K) are based on analyses that require estimates of the soil water flux and the pressure head (h) gradient. These analyses typical-

ly involve differencing of field-measured pressure head (h) and volumetric water content (theta, th) data, a process that can significantly amplify instrumental and measurement errors. More reliable methods result when differencing of field data can be avoided. One such method is based on estimates of gravity drainage curve K'(th) = dK/dth, which may be computed from observations of th and/or h during the drainage phase of infiltration drainage experiments assuming unit gradient hydraulic conditions. The present study compared estimates of unsaturated soil hydraulic functions on the basis of different combinations of field data th, h, K, and K'. Five different data sets were used: (1) th-h, (2) K-th, (3) K'=th, (4) K-th-h, and (5) K'-th-h. The analysis was applied to previously published data for the Norfolk, Toup, and Bethany soils. The K-th-h and K'-th-h data sets consistently produced nearly identical estimates of the hydraulic functions. The K-th-h and K'-th data also resulted in similar curves, but results were less consistent than tions. The A-th and A-th data and resulted in similar curves, but results were less consistent than those produced by K-th-h and K-th-h data sets. These results demonstrate that differencing of field data can be avoided and that there is no need to data can be avoided and that there is no need to calculate soil water fluxes and pressure head gradi-ents from inherently noisy field-measured th and h data. The gravity drainage analysis also provides results over a much broader range of hydraulic conductivity values than is possible with the more standard instantaneous profile analysis, especially when augmented with independently measured soil water retention data. HYDROLOGICAL CONSEQUENCES OF ARTI-FICIAL DRAINAGE OF GRASSLAND.

Ministry of Agriculture, Fisheries and Food, Cambridge (England). Field Drainage Experimental

A. C. Armstrong, and E. A. Garwood. Hydrological Processes HYPRE3, Vol. 5, No. 2, p 157-174, April/June 1991. 9 fig, 7 tab, 33 ref,

Descriptors: \*Drainage, \*Grasslands, \*Soil water, \*Surface runoff, \*Waterlogging, Flood peak, Rainfall infiltration, Soil porosity, Water loss, Water

Water in the soil is a major factor affecting the growth and utilization of grass in agricultural systems. Although grass requires adequate supplies of water to maintain its growth, excess water will retard growth by waterlogging of the roots. Consequently, artificial drainage offers the potential for improving the productivity of grassland by in-

#### Group 2G-Water In Soils

creasing the grass yield and the length of the grazing season. Soil water regimes and water balances were evaluated for a series of drained and undrained experimental grassland plots to examine the agronomic consequences of drainage. Although drainage has lowered the water tables and reduced the duration of waterlogging in the drained plots, its effects in terms either of the total water quantities leaving the site or of peak flows is drained piots, its erfects in terms either of the total water quantities leaving the site or of peak flows is quite small. The major effect of drainage is to alter the route of water leaving the site. In its undrained state, the soil is waterlogged for the majority of the winter, incident rainfall cannot infiltrate, and water as surface runoff or near-surface flow. However, the introduction of fissures by mole drainage ever, the introduction of fissures by mole drainage both provides an outlet and enhances the macro-porosity, so that the rain moves rapidly through the soil and appears as drainflow. Consequently, the additional delay in generating peak runoff through the drainage system is only of the order of 30 minutes on the experimental plots. (Korn-PTT) W91-11347

A large number of soil moisture measurements have been compiled from an observations network in the USSR. These data can be used to test parameterizations of hydrological processes employed in climate models. Soil moisture simulations for the current climate from general circulation models (GCMs) are not adequately realistic, making it difficult to accept mode-based conclusions of possible changes of soil moisture induced by anthropogenic global warming. Measurements for the period 1972-1985 give rather large values for the linear trend of soil moisture in the upper 1-m soil layer. The seasonal pattern of soil moisture does not correspond to the summer desiccation of continents scenario. Empirical data sets were found to confirm previously tested theoretical conclusions which stated that the spectrum of tempo-A large number of soil moisture measurements clusions which stated that the spectrum of temporal variations of soil moisture correspond to a fistorder Markov process with the decay time scale being equal to the ratio of field capacity to poten-tial evaporation. SOLUTION IN CLOSED FORM AND A SERIES SOLUTION TO REPLACE THE TABLES FOR THE THICKNESS OF THE EQUIVALENT LAYER IN HOOGHOUDT'S DRAIN SPACING

LAYER IN HOOGHOUDI'S DRAIN SPACING FORMULA. Agricultural Univ., Wageningen (Netherlands). W. H. van der Molen, and J. Wesseling. Agricultural Water Management AWMADF, Vol. 19, No. 1, p. 1-16, January 1991. 3 fig, 2 tab, 13 ref, 7 appeared.

Descriptors: \*Computer models, \*Computers, \*Drain spacing, \*Drainage engineering, \*Flow models, \*Soil water, \*Subsoil drainage, Dagans formulat, Hooghoudts formula, Mathematical

The steady-state drainage equation of Hooghoudt is extensively used to find drain spacings, but it has the drawback that tables for the determination of the so-called 'equivalent layer, d' are needed. These tables were based on numerical approxima-tions, and nomographs were extensively used for name of age, where read-nomography an obsolete art, these methods have lost their appeal. A solution in closed form involv-ing theta-functions and a series solution to design purposes. In the computer age, where read-ing of tables has become a difficult operation and the tables for the thickness of the equivalent layer in Hooghoudt's drain spacing formula are presented. A series solution is far better suited for electronic computations; however, for thin aquifers their convergency is slow. In this case Dagan's formula is very accurate. A combination of both types of solutions provides an efficient algorithm. (Feder-PTT) W91-11430

EFFECT OF LOW SALINITY WATER ON SALT DISPLACEMENT IN TWO SOILS.

DISPLACEMENT IN TWO SOILS. Cairo Univ., Giza (Egypt). Faculty of Agriculture. A. M. Helalia, S. El Amir, A. A. Wahdan, and M. E. Shawky. Agricultural Water Management AWMADF, Vol. 19, No. 1, p 43-50, January 1991. 4 fig. 2 tab, 15 ref.

Descriptors: \*Conductivity, \*Hydraulic conductivity, \*Irrigation water, \*Saline soils, \*Salinity, \*Soil dynamics, Electrolytes, Leaching, Loam, Sand, Sodium, Soil chemistry, Soil physics, Soil texture.

Two soils, sandy and sandy loam, were leached with four displacing solutions in a laboratory experiment. The initial salinity of the saturation extract was 8.0 and 8.4 dS/m for the sandy and sandy loam soil, respectively. The electrical conductivity (EC) of the synthesized solutions (NaCl + CaCl2) was 2.1, 1.4, and 0.55 dS/m at sodium adsorption ratio (SAR) equal to 5, whereas the fourth solution (0.1 dS/I) consisted of distilled water. The solutions were used in sequence from high to low EC. The total volume of leachate with the sandy soil was about 44 pore volumes (PV), compared to about 21 PV with sandy loam soil in order to reach an equilibrium with the lowest EC solution used. an equilibrium with the lowest EC solution used. The time required for that equilibrium was 7.3 and 668.5 hours for the sandy loam soil, respectively. The lower hydraulic conductivity (K) and the long time required to equilibrate the sandy and sandy loam soil with low salt solution increased the leaching efficiency due to the complete mixing het many the displaced solution. between the displacing and displaced solution before displacement occurs. The high K and the short time needed to equilibrate the sandy soil caused partial mixing between the solutions and decreased partial mixing between the solutions and decreased the leaching efficiency. In both soils the low salinity water reduced the water movement and it took a large volume of water to lower the EC of leachate to a certain level. Therefore, the use of low salinity water for irrigation should be handled with care. (Author's abstract)

Descriptors: \*Cultivation, \*Decomposing organic matter, \*Ecological effects, \*Soil organic matter,

\*Soil organisms, Biomass, Fertility, Food chains, Meadows, Mineralization, Species composition.

Studies were undertaken to demonstrate that changes in the humus content of soil are usually associated with changes in the number and biomass of soil fauna. Ecosystem disturbances such as cultior son rauna. Ecosystem disturbances such as culti-vation, clear-cutting, or swamp damage, are fol-lowed by a decrease in the content of organic matter and the number of animals in soil. More-over, the highest rate of humus decrement is assoover, the highest rate of numus decrement is asso-ciated with the greatest decrease in soil fauna. The decrease in organic matter involves not only a reduction of animal biomass, but also deep changes in the structure of animal communities. Size and individual weight decrease, while the trophic structure is transformed towards higher proporstructure is transformed towards higher propor-tions of herbivores and saprophages, which stimu-late the mineralization of organic matter. At the same time, species diversity diminishes. Long-term data from meadows and arable fields showed a positive correlation between humus content and biomass of soil fauna. However, although the data biomass of soil fauna. However, although the data indicate that fauna biomass and humus content are closely interrelated, they do not indicate the mechanism by which soil fauna affects humus. Results show that, if the decomposition of organic matter takes place under similar habitat conditions, then more humus is formed in the site rich in soil fauna may be concluded that agricultural treatments that pauperize the soil fauna simulta-neously cause a decrease in the organic matter content in soil, adversely affecting one of the cru-cial factors in soil fertility. POTENTIAL IMPACTS OF CHANGE ON THE GREAT LAKES. OF CLIMATE

Environmental Protection Agency, Washington, DC. Office of Policy, Planning and Evaluation. J. B. Smith

Bulletin of the American Meteorological Society BAMIAT, Vol. 72, No. 1, p 21-28, January 1991. 3 fig, 3 tab, 32 ref.

Descriptors: \*Carbon dioxide, \*Climate changes, \*Global warming, \*Great Lakes, \*Lakes, Environmental effects, Ice cover, Lake management, Political aspects, Productivity, Shipping.

Global climate change could have a significant impact on the Great Lakes. A number of studies of the potential effects of climate change on the Great the potential effects of climate change on the Great Lakes were commissioned by the U.S. Environ-mental Protection Agency, using common scenar-ios of global warming derived mainly from general circulation models. These studies found that a dou-bling of carbon dioxide concentrations in the at-mosphere could eventually lower Great Lakes water levels by 0.5 to 2.5 m; reduce ice cover by 1 to 2.5 months: lengthen shipping, seasons while to 2.5 months; lengthen shipping seasons while increasing shipping and dredging costs; reduce dissolved oxygen levels in shallow lake basins; and increase fish productivity. Measures should be taken in the near future to anticipate many of these impacts and mitigate their effects or avoid costly political issues. (Author's abstract) W91-10480

PERSPECTIVES FOR ECOLOGICAL MODEL-LING OF TROPICAL AND SUBTROPICAL RESERVOIRS IN SOUTH AMERICA.

Lakes-Group 2H

Basic characteristics of tropical and subtropical reservoirs in South America examined. The baseline environment is considered the reservoir area and the hydrographic basin, including the region downstream. For the modelling effort it is neces-sary to establish a conceptual framework based on downstream: a conceptual framework based on the following characteristics: morphometry and compartments, retention time; hydrological cycle and flow requirements; reservoir; reservoir thermal stratification and circulation patterns; quantification of submerged forest biomass and its degradation in reservoirs located in the tropical rainforest; discalled avoyage consumption: potential for cudissolved-oxygen consumption; potential for eu-trophication and loading capacity; pulses in forcing functions; and suspended-material transport. In the tunctions; and suspended-material transport. In the region downstream it is necessary to consider river recovery capacity, water uses and flow regime requirements. Most reservoirs in this latitudinal gradient follow a significantly different path from the reservoirs in temperate zones, including effects of forcing functions, decomposition rates, and seasonal circulation periods. The size, volume and dimension of these large artificial ecosystems, justify the implementation of several methodological approaches useful for modelling. including oceanoapproaches useful for modelling, including oceano-graphic techniques and intensive use of satellite images. Rates of processes in tropical ecosystems are not well known, and such input from experi-mental limnology will be an important step as a basis for the modelling effort. The organization of basis for the modeling entort. The organization of a data bank for these reservoirs is in progress, and such a system is also fundamental for the modelling procedure. The modelling effort for tropical reservoirs is mainly due to the need for evaluation of effects, prediction of eutrophication, prognosis for possible deterioration of water quality in reservoirs with inundated forest, and introduction of management techniques for multiple uses including upstream/downstream environments. Management techniques include exploitation of spatial heteroge-neity, regulation of retention time and optimal biomass. (Author's abstract) W91-10487

Ecosystems can be described as networks of flows Ecosystems can be described as networks of flows of material and energy. A measure to quantify the growth and development of an ecosystem is systems ascendency. Growth is represented by the increase in total system throughput and development by the increase in the average mutual information of the network structure. To incorporate temporal dynamics into the systems ascendency, the static invocidimensional flow network is extemporal dynamics into the systems ascendency, the static two-dimensional flow network is extended into a third dimension—that of time. System ascendency is now calculated, using time-varying probabilities, resulting in what is called time-dependent ascendency. The time-dependent ascendency is a sensitive measure for the organization of the dynamic network structure in the dimension of the dyn time. This is demonstrated by using a simple two-level ecosystem model. Optimization of the timedependent ascendency is suggested as a selection criterion for the succession of species in the seasonal cycle. Especially in the aquatic environment, where environmental and biological variability are of utmost importance, a new perspective from the viewpoint of a dynamic network structure could provide new insights into general laws of ecosys-tem function. The Mediterranean Sea is considered by many as one of the less productive seas of the world. Due to geophysical and arid climatic conditions, the eastern Mediterranean is the most oligotrophic part of the sea. After the opening of the Aswan Dam in 1965, the major nutrient contribution to the Medi-terranean was considerably diminished. Several cruises and laboratory studies of the pelagic waters off the Israel shore indicated that the eastern Mediterranean is comparable with the most oligotrophic parts of open oceans. The neritic waters, overlying the narrow continental shelf (10 to 20 km), were the narrow continental shelf (10 to 20 km), were much more productive than the pelagic waters, having on average three times the chlorophyll concentration and five times the primary production of the pelagic waters. However, even the neritic zone is very unproductive as compared to similar regions of the world. The total catch of marine fishes, not surprisingly, along the Israeli coast is only a few thousand tons annually. (Author's abstract) thor's abstract) W91-10553

FATE OF SILICATE MINERALS IN A PEAT

BOG. Texas Univ. at Austin. Dept. of Geological Sci-P. C. Bennett, D. I. Siegel, B. M. Hill, and P. H.

Glaser.
Geology GLGYBA, Vol. 19, No. 4, p 328-331, April 1991. 3 fig. 1 tab, 22 ref. American Chemical Society Petroleum Research Fund No. ACSPRF 19582-AC2.

Descriptors: \*Peat bogs, \*Silica, \*Silicates, \*Water chemistry, \*Wetlands, Chemical interactions, Chemical reactions, Coal, Cores, Diatoms, Equilibrium, Geohydrology, Hydrogen ion concentration, Interstitial water, Minnesota, Organic acids, Peat, Piezometers, Quartz, Silicon, Solubility.

Pore waters in marine and lacustrine sediments often contain dissolved silicon well in excess of the onen contain dissolved silicon well in excess of the equilibrium solubility of quartz. The source of that silicon is often presumed to be from dissolving amorphous silica, or from soluble silicate minerals. However, in some organic-rich environments, quartz solubility is unusually high. An investiga-tion was undertaken to study the sort under the quartz solubility is unusually high. An investiga-tion was undertaken to study the pore water chem-istry, solid phase chemistry, and silicate-silt surface textures for a peatland in northern Minnesota. The results of the study revealed that quartz and alu-minosilicates rapidly dissolve in anoxic, organic-rich, neutral-pH environments. In the peat bog,

normally a recharge mound, dissolved silicon in-creases with depth as pH increases, exceeding the creases with depth as pri increases, exceeding the background silicon concentration by a factor of two. Silicate grain surfaces, including quartz, are chemically etched at this location, despite being in contact with pore water at neutral pH with dissolved silicon well above the equilibrium solubility of quartz. The increasing silica concentrations at of quartz. The increasing silica concentrations at circum-neutral pH are consistent with a system where silicate solubility is influenced by silica-organic acid complexes. Silica-organic acid complexes, therefore, may be the cause of the almost complete absence of diatoms in decomposed peat and contribute to the formation of silica-depleted underclays commonly found beneath coal. It is suggested that new impoundments undergo an initial period of trophic upsurge lasting one to three years because of organic detritus and inor-ganic nutrients from the inundated basin. The new Monksville Reservoir in Passaic County, New Monksville Reservoir in Passaic County, New Jersey, provided an opportunity to study the accelerated transformation of the Wanaque River into a 200-ha lake and to compare productivity with the older Wanaque Reservoir located immediately downstream. A one-year investigation of both reservoirs was conducted during 1988. The primary productivity (0.547 g C/sq m/d) of the new Monksville Reservoir was not significantly different from that of the established Wanaque Reservoir (0.668 g C/sq m/d). Mean surface chlorophyll a concentrations were similar (3.0-4.0 micrograms/L), although the Monksville Reservoir cathibited more pronounced chlorophyll peaks in spring and L), although the Monksville Reservoir exhibited more pronounced chlorophyll peaks in spring and late autumn. Phytoplankton and 200plankton populations were consistently larger and fluctuated sharply in the Monksville Reservoir. Both reservoirs became thermally stratified, but only the Monksville Reservoir developed a metalimnetic dissolved oxygen minimum. The results demonstrated that the predicted trophic upsurge in the new reservoir did not occur in the first year. Therefore, the ecosystem dynamics did not fit the model for larger reservoirs. Atmospheric scientists have predicted that large-scale climatic changes will result from increasing levels of tropospheric CO2. The potential effects of climate change on primary productivity has been investigated in Castle Lake, a mountain lake been investigated in Castle Lake, a mountain lake in Northern California. Annual algal productivity was modeled empirically using 25 years of limnological data in order to establish predictive relationships between productivity and the climatic variables of accumulated snow depth and precipitation. The outputs of monthly temperature and precipitation from three general circulation models (GCMs) of doubled atmospheric CQ2 were then used in the tion from time general circulation modes (GCMS) of doubled atmospheric CO2 were then used in the regression model to predict annual algal productivity. In all cases, the GCM scenarios predicted increased algal productivity for Castle Lake under conditions of doubled atmospheric CO2. The primary cause of enhanced productivity was the increased length of the growing season resulting form earlier spring ice-out. (Author's abstract) W91-10819

OCCURRENCE OF A SOUTH AMERICAN AR-MORED CATFISH IN THE HILLSBOROUGH

RIVER, FLORIDA.
Florida Dept. of Natural Resources, Clermont.
M. E. Ludlow, and S. J. Walsh.
Florida Scientist FLSCAQ, Vol. 54, No. 1, p 4850, Winter 1991. 1 tab, 6 ref.

Descriptors: \*Catfish, \*Fish establishment, \*Fish populations, \*Florida, Canals, Hillsborough River.

Although loricariid catfishes have been reported Although Ioricariia cattisnes have even reported from the Tampa Bay area for several decades, until recently they had not been demonstrated from the Hillsborough River drainage, Hillsborough County, Florida. The construction of a new canal. system may have allowed ingress of the South American catfish Pterygoplichthys cf. multiradia-tus into the Hillsborough proper. Accurate identifi-cation of this exotic species is difficult because of the unresolved toxonomy of hypostomine loricar-iids, and since the area in South America where the Hillsborough River population originally came from is unknown. Casual observations indicated that Pterygophichthys is presently abundant in Hillsborough State Park. Their worm-like feces are conspicuous in shallow areas of the river bottom. conspicuous in snattow areas of the river obttom. Eutrophication of the river which has resulted in heavy algal growth on benthic substrates has prob-ably been beneficial to this species. The potential impact of this exotic catfish on the community ecology of the river is unknown. Therefore, future research into the biological and ecological impacts of this algae-feeding armored catfish is recommended. (Author's abstract)

LONGITUDINAL DEVELOPMENT OF MA-CROINVERTEBRATE COMMUNITIES BELOW OLIGOTROPHIC LAKE OUTLETS. laho State Univ., Pocatello. Dept. of Biological

Great Basin Naturalist GRBNAR, Vol. 50, No. 4, p 303-311, December 1990. 6 fig, 2 tab, 8 ref.

Descriptors: \*Benthic fauna, \*Lake ecology, \*Lim-nology, \*Macroinvertebrates, \*Oligotrophic lakes, Aquatic habitats, Outlets, Particulate matter, Population dynamics, Seston, Species composition, Species diversity.

Benthic macroinvertebrates were collected at several sites downstream of three oligotrophic lake outfalls in July 1986. Total numbers, biomass, and species richness increased rapidly immediately downstream from the outlets, and then either stabilized or continued to increase downstream in parallel with benthic organic matter standing crops. Filter feeder densities showed an initial buildup and then decline downstream from the outlets. Variability in longitudinal patterns of other func-Variability in longitudinal patterns of other func-tional feeding groups among lake outlets was relat-ed to differences in food quantity and quality, and microhabitat. An additional set of samples was collected at Pettit Lake outlet in August 1986. Species richness and total density peaked sooner under baseflow conditions in June. Distributions of all functional feeding groups, except filter feeders, also differed between the two periods, reflecting differences in the obvisical environment. Reduced differences in the physical environment. Reduced differences in the physical environment. Reduced lentic inputs of particulate organic matter seston and improved habitat suitability downstream may be responsible for the progressive development of macroinvertebrate communities in oligotrophic lake outlets. These data imply the importance of the habitat templet in the structuring of benthic communities. (Author's abstract) W91-10856

ZOOPLANKTON EFFECTS ON PHYTO-PLANKTON IN LAKES OF CONTRASTING TROPHIC STATUS.

California Univ., Davis. Div. of Environmental J. J. Elser, and C. R. Goldman.

Limnology and Oceanography LIOCAH, Vol. 36, No. 1, p 64-90, January 1991. 12 fig, 6 tab, 49 ref.

Descriptors: \*California, \*Lake ecology, \*Limnology, \*Phytoplankton, \*Primary productivity, \*Trophic level, \*Zooplankton, Algae, Chlorophyll, Eutrophic lakes, Food chains, Grazing, Oligotrophic lakes, Phosphorus, Waterfleas.

Studies were carried out in three lakes of strongly contrasting trophic state to evaluate how the effects of zooplankton on phytoplankton vary as a function of lake productivity. Chlorophyll and total P concentrations differed by 2-3 orders of magnitude among ultra-oligotrophic Lake Tahoe, meso-oligotrophic Castle Lake, and strongly eutrophic Clear Lake. Three experimental designs involving short-term (4.0) manipulations of nutrients volving short-term (4 d) manipulations of nutrients, ambient zooplankton, and the common crustacean amoient zoopianston, and the common crustacean grazer Daphnia were performed in each lake. Algal responses were assessed at both the aggregate, community and species levels. Experiments in Lake Tahoe revealed a high degree of nutrient sensitivity but negligible grazing impacts by the very low densities of ambient zooplankton. Daphnia grazing had substantial impacts on Tahoe phytoplankton, indicating high supervibility to general parts of the properties of th toplankton, indicating high susceptibility to graz-ing in this assemblage of relatively small-sized algal species. Castle Lake exhibited strong direct and species. Castle Lake exhibited strong uncer and indirect impacts of both ambient zooplankton and Daphnia on the nutrient-limited algal assemblage. Dapnia on the nutrient-imited aigal assemblage. The cyanobacteria-dominated algal community of Clear Lake was resistant to grazing impacts, re-sponding relatively weakly only to the higher den-sities of Daphnia. Good correspondence between

estimates of algal biomass made from chlorophyll measurements and microscopic examination were obtained, and, in Castle Lake, concordance between estimated community productivity turnover tween estimated community productivity turnover times made from species-specific growth determinations and community productivity measurements was observed. The contrasting responses to experimental zooplankton manipulations in the three lakes support the view that the coupling between zooplankton and phytoplankton is strongest in the lakes of intermediate productivity and imply that food-web alterations at the top of the food web are most likely to propagate to the level of the phytoplankton (and therefore lake water quality) in lakes of moderate trophic status. (Author's abstract) W91-10859

SECCHI DISK AND PHOTOMETER ESTI-MATES OF LIGHT REGIMES IN ALASKAN LAKES: EFFECTS OF YELLOW COLOR AND TURBIDITY.

Alaska Dept. of Fish and Game, Soldotna. Fisher-ies Rehabilitation, Enhancement and Development

J. P. Koenings, and J. A. Edmundson.

Limnology and Oceanography LIOCAH, Vol. 36, No. 1, p 91-105, January 1991. 6 fig, 7 tab, 54 ref.

Descriptors: \*Alaska, \*Color, \*Lakes, \*Limnology, \*Photometry, \*Secchi disks, \*Transparency, \*Turbidity, Chlorophyll, Light penetration, Particulate matter, Trophic level.

Variations in underwater light regimes among 58 Alaskan lakes were indexed by Secchi disk (SD) transparency and by vertical attenuation coeffi-cients (K-d) and euphotic zone depths (EZD) decients (K-d) and euphotic zone depths (EZD) derived from using a submarine photometer (SP) sensitive to photosynthetically active radiation (PAR). Lake-specific ratios between turbidity (light scattering) and color (light absorption) explained 52% of the variation (P<0.0001) in K-d x SD values, which ranged as a continuum between 0.52 and 3.8. A clear-water median value of 1.86 (range, 1.13-3.26) is elevated by color to a median of 2.70 (range, 1.81-3.83), whereas turbidity reduces the median value of 0.93 (range, 0.52-2.56). EZD:SD, PAR at the SD depth, and PAR reflection (backscatter) also changed with the turbidity to-color ratio. The nearly 10-fold ranges between K-d x SD (0.59-4.09) and EZD:SD (0.89-8.67) values taken from 35 studies on lakes, estuaries, values taken from 35 studies on lakes, estuaries, and oceans could be explained by color and turbidand oceans could be explained by color and turbidity differences. Background attenuation from small amounts of color (< 10 Pt units) and turbidity (<5 NTU) uncoupled SD and SP measurements from changes in chlorophyll a, limiting their use as an index of trophic state. Changes in K-d x SD can serve, however, as a useful index of system loading by turbid particulate material or organic color. (Author's abstract)

ROLE OF SEASONAL TURNOVER IN LAKE ALKALINITY DYNAMICS.

Marine Biological Lab., Woods Hole, MA. Ecosystems Center. G. W. Kling, A. E. Giblin, B. Fry, and B. J.

Limnology and Oceanography LIOCAH, Vol. 36, No. 1, p 106-122, January 1991. 6 fig, 5 tab, 40 ref.

Descriptors: \*Alkalinity, \*Lake sediments, \*Lakes, \*Limnology, \*Massachusetts, \*Turnover time, Cores, Hydrogen sulfide, Nitrification, Oxygenation, Seasonal variation, Stratification, Sulfates, Sulfides, Water chemistry.

Elemental cycles and alkalinity (Alk) production and consumption were studied in sediments from two ponds (Mares and Gull) in coastal Massachusetts. Intact cores were incubated in the laboratory and manipulated to simulate water-column anoxia and manipulated to simulate water-commit anotate stratification and oxygenation during turnover. Reactions with S dominated Alk budgets in Mares Pond, whereas in Gull Pond reactions with N contributed most to Alk change. In Mares Pond, control cores held anoxically produced Alk at an average rate of 2.66 +/-0.59 (SE, N=3) meq/sq m/d, mostly due to sulfate reduction. This rate was

# Lakes-Group 2H

similar to calculations from hypolimnetic monitorsimilar to calculations from hypolimnetic monitoring in the pond during summer stratification. In cores from Mares pond where the water column was aerated to simulate turnover, the reoxidation of S (1.3 meq sulfate/sq m/d) contributed most to consumption of Alk (3.5 meq/sq m/d); half of all Alk lost during the 40-d experiment was consumed in the first 4 d of turnover. In aerated cores from Gull Pond, Alk consumption (4.2 meq/sq m/d) was driven mostly by white first to the consumption (4.2 meq/sq m/d). was driven mostly by nitrification (2.8 meq/sq m/d). High rates of Alk consumption observed in oxidized cores illustrate the potential for rapid Alk loss during seasonal turnover. Pore water profiles of sulfate and Alk suggest that sulfide oxidation was strongest in the top 1 cm of sediment and reached to a depth of 3-4 cm. Oxidation occurred rapidly in response to turnover, and although H2S may have been oxidized initially, the oxidation of solid-phase species dominated after 1 or 2 d. An isotopic mass balance of S in two turnover cores showed that from 30-70% of the oxidized S originated as inorganic rather than organic S. (Author abstract) W91-10861

EFFECTS OF PH AND ALUMINUM ON THE GROWTH OF THE ACIDOPHILIC DIATOM ASTERIONELLA RALFSII VAR. AMERICANA. Michigan Univ., Ann Arbor. Dept. of Biology.

R. W. Gensemer. Limnology and Oceanography LIOCAH, Vol. 36, No. 1, p 123-131, January 1991. 3 fig, 3 tab, 30 ref.

Descriptors: \*Acid lakes, \*Acid rain effects, \*Aluminum, \*Diatoms, \*Phytoplankton, \*Toxicity, \*Water pollution effects, Algal growth, Copper, Hydrogen ion concentration, Iron, Toxicology.

The effects of pH and Al on the acidophilic diatom The effects of pH and Al on the acidophilic diatom Asterionella ralfsii var. americana were examined in axenic batch cultures. Experiments were performed under conditions of both high (pH 5) and low (pH 6) Al solubility over a range of concentrations from 0 to 30 micromoles/L total Al. Growth rates were analyzed with respect to analytically determined Al concentrations and to predicted changes in dissolved metal ion speciation in response to Al additions. Growth rates of A ralfsii e to Al additions. Growth rates of A. ralfsii were significantly reduced above 15 micromoles/L were significantly reduced above 15 merolinores Let total Al at both pH 5 and 6. Al additions increased estimated free ion activities of Al(3+), Fe(3+), and Cu(2+) through indirect chelator interactions at pH 5 and 6; therefore, all three were significantly correlated with growth rate reductions. Indely correlated with growth rate reductions. Inde-pendent manipulations of total Fe and Cu, howev-er, suggested that Al was not directly increasing either Fe or Cu free ion activities to toxic levels. Relationships of growth rates to both inorganic monomeric Al and to estimates of pAl were strongly pH-dependent with toxicity being greater per unit of dissolved Al concentrations at pH 6 than at pH 5. These results are consistent qualita-tively with predictions that H(+) ions can amelio-rate dissolved metal toxicity by competitively extively with predictions that H(+) ions can ameliorate dissolved metal toxicity by competitively excluding Al(3+) ions from binding to cell surface ligands. The impact of Al on natural phytoplanton populations therefore is likely to depend on a combination of pH-dependent Al solubility, the protonation of cell-surface ligands, and chelator-mediated metal speciation. ESTIMATION OF PHOSPHORUS EXCHANGE BETWEEN LITTORAL AND PELAGIC ZONES DURING NIGHTTIME CONVECTIVE CIRCU-LATION.

LATION.
Army Engineer Waterways Experiment Station, Spring Valley, WI. Eau Galle Lab.
W. F. James, and J. W. Barko.
Limnology and Oceanography LIOCAH, Vol. 36, No. 1, p, January 1991. 7 fig, 2 tab, 23 ref.

Descriptors: \*Lakes, \*Limnology, \*Littoral zone, \*Nutrient transport, \*Pelagic zone, \*Phosphorus, \*Water circulation, \*Wisconsin, Convection, Diurnal variation, Eau Galle Reservoir, Reservoirs,

A fluorescent dye was used in Eau Galle Reservoir, Wisconsin, to examine nighttime convective circulation patterns and exchanges of P between

the littoral and pelagic zones during 25-26 July and 12-13 September 1988. Cooler littoral bottom water moved into the pelagic zone at night as an interflow at 2.5 m in July and at 4.0 m in September. Warmer pelagic water moved into the littoral zone as a surface flow during both periods. The littoral zone exhibited high total P concentrations above the sediment in July, but much lower concentrations in September. Estimated net areal total P flux to the pelagics zone was 18. mg/sq m/d in P flux to the pelagioc zone was 1.8 mg/sq m/d in July but only 0.2 mg/sq m/d in September. Net areal total P flux in July accounted for about 22% of the summer average, lakewide internal total P load to the reservoir. The results suggest that load to the reservoir. The results suggest that circulation patterns induced by nighttime convective cooling are of potentially great importance to the P economy of this reservoir. Although P transport to the pelagic zone occurs primarily at intermediate depths near the base of the epilimnion, this source is available to migrating algal species, which are abundant in the reservoir. For ectothermic organisms in thermally stratified bodies of water, temperature provides a strong and unambiguous environmental signal. Juvenile sock-eye salmon in Quesnel Lake were nocturnally thermoselective and distributed in a narrow vertical band within the thermocline. Differences in vertical position across and between lake transects occurred when an internal seiche was active, as evi curred when an internal sectice was active, as evidenced by a short-term alteration in the thermal structure of the lake. Although juvenile sockeye altered their nocturnal vertical positions by several meters in response to the internal seiche, this displacement probably had only minor or insignificant effects on their growth and survival in the lake. The wave-induced nocturnal displacement was a considerable of the control of the contro small compared to the 50-80 m vertical ampliturde of diel vertical migration by juvenile sockeye within the system. The findings emphasize the importance of temperature controlling the noctrunal distribution of juvenile sockeye since selection behavior has important metabolic implications for the fish. VISUAL INTERPRETATION OF A LANDSAT MOSAIC OF THE OKAVANGO DELTA AND SURROUNDING AREA. School of Agriculture, University of Bophuthats-

wana, South Africa. J. P. Watson.

Remote Sensing of the Environment RSEEA7, Vol. 35, No. 1, p 1-9, January 1991. 5 fig, 7 ref.

Descriptors: \*Botswana, \*Geomorphology, \*Landsat images, \*Okavango Delta, \*Remote sensing, \*Terrain analysis, \*Wetlands, Climatology, Deltas, Land use, Satellite technology, Surface

A mosaic of the Okavango delta and surrounding areas in Botswana was prepared from 4 color composite Landsat images. The Okavango River enters the swamp zone near the Botswana border. The first 130 km of the swamp is confined to a narrow trough known as the panhandle and then the river spreads out into a number of distributors. ies to form the delta. The climate of the area is semiarid; about 90% of the rainfall comes in the summer months from November to March. The winter months from June to September are mild and dry. Potential evaporation over the delta is high. The delta has an inflow of about 11 billion cubic meters a year and an average rainfall of 500 cubic meters a year and an average rannal or norm, or 5 billion cubic meters, a year. Flow in the Okavango delta formerly extended over a greater area than at present. The retreat of the water may be the result of several causes, including a reduction in rainfall in Angola or the delta. The Okavango delta and surrounding arga lies at an elevation in rainian in Angola or the detail. The Oka-vango delta and surrounding area lies at an eleva-tion of 850-1000 m. It comprises two major geo-morphological features: the Kalahari sand plain and the Okavango-Linyati depression. The study area is divided into several terrain types: swamp, area is divided into several terrain types; swamp, alluvium, lacustrine deposits, Kalahari sand plain, sand dunes, and bedrock. The three main types of land use are livestock grazing, wildlife, and arable. Livestock grazing and wildlife areas occupy 99% of the region and carry a cover of natural or seminatural vegetation related to the main terrain units. Thus the perennial swamp is characterized by the contribute sets of the seminatural series. by aquatic vegetation, the seasonal swamp is mostly grassland, and the Kalahari sand plains carries woodland. The small proportion of arable land is found mainly along drainage lines and in the seasonal swamp. (Sand-PTT) W91-10879

DELAY IN LAKE RECOVERY CAUSED BY IN-TERNAL LOADING.

A simplified model of the lake-sediment system is A simplified model of the lake-sediment system is proposed, which aims to predict the long-term evolution and the recovery time of eutrophied lakes. The model represents the state of lake and sediment each by means of a single variable. Having recourse to a well-defined set of assumptions for sediment processes, and adopting time dependent coefficients, the model balance equations can be solved analytically, and the evolution of the state variables towards steady-state condi-tions, can be discussed in terms of characteristic times of the considered system. Particular attention times of the considered system. Particular attention is devoted to the consequences of P saturation of the solid phase in surface sediment layers, i.e., to a situation which is frequently present in eutrophied lakes. The model is applied to the case of the highly eutrophied Lake Varsee (Northern Italy), in which internal P loadings from sediments appear to be substantial. Taking into account the coupling between lake and sediments, the time needed to attain the steady-state P concentration compatible with the present P loadings is evaluated as about 5 times the water renewal time of the lake. It is also shown to what extent the assumptions on sediment dynamics affect the model predictions. (Author's abstract)

MICROCYSTIS CHANGES ITS BUOYANCY IN RESPONSE TO THE AVERAGE IRRADIANCE IN THE SURFACE MIXED LAYER,

A number of gas-vacuole planktonic cyanobacteria have been shown to become more buoyant when exposed to light of low irradiance and to lose buoyancy and sink at high irradiance. By respond-ing in this way, colonial bloom-forming cyanobac-

# **Group 2H—Lakes**

teria like Microcystic aeruginosa may undergo marked diurnal changes in vertical distribution in lakes. A series of experiments and observations were performed on a Microcystis population in Vinkeveen Lake, in the Netherlands. Samples were Vinkeveen Lake, in the Netherlands. Samples were taken for the analysis of carbohydrate, protein, chlorophyll-a, cell turgor pressure, relative gas vesicle volume, buoyant density, buoyancy state, and colony concentration. Measurements of photosynthetically active photo irradiance were made at wavelengths between 400 and 700 nm. The microcystis colonies circulated within the surface mixed layer whose depth (usually 2 to 4 m) usually ex-ceeded the euphotic depth (usually less than 1.5 m) in this wind-exposed lake. Colonies held in bottles in this wind-exposed lake. Colonies held in bottles at the lake surface responded to the high irradiance by losing their buoyancy, while those at greater depths remained buoyant. For colonies circulating within the surface layer the degree of buoyancy loss that occurred during the day depended on the mean irradiance to which they were exposed, which could be determined from the average surface. which could be determined from the average sur-face irradiance, the mixed depth and the vertical extinction coefficient. Buoyancy loss was also cor-related, but less strongly, with the proportion of the daytime spent by colonies within the euphotic zone. Surface scums were usually prevented from forming by wind mixing. The diel variations of biochemical particulate parameters (proteins, carbohydrates, lipids, adenine nucleotides, chlorophyll-a) together with metabolic indicators (primary producers, adenylate energy charge) as well as population variables (algal species composition) and nutrient availability in lacustrine environments were investigated. This was an effort to study the combined effects of these parameters on the diel biochemical changes of particulates in two trophically different lakes: Aydat and Pavin lakes in Massif Central, France. Aydat Lake is a dimictic eutrophic lake, and Pavin is a meromictic (mixmomnimoliminon at 55 m) and dimictic mictic (mixomonimolimnion at 55 m) and dimictic (with partial overturns) oligo-mesotrophic lake.
Nitrogen concentration in the water appears to play a major role in controlling algal metabolism.
Lack of nitrogen induces accumulation of reserve products during the day and their use in the night when oxidative phosphorylation prevails and pho-tophosphorylation is absent. (Agostine-PTT) W91-10896

Biomass, Competition, Dynamics, Organic carbon, Particulate matter, Plankton, Seasonal variation.

An inverse relationship between the abundance of rotifers and large daphnids has been documented. Grosser Binnensee, a shallow lake in Northern Germany, was inhabited by an interesting population of Daphnia magna in 1987. During a study of the zooplankton as part of a detailed investigation of the lake, a field example of the inverse relationship of Daphnia and rotifers was discovered. The seconal duranties of these two components of the seasonal dynamics of these two components of the zooplankton community were analyzed. Several cycles occurred during one year in the same lake, so that repetitive analyses of the Daphnia-rotiferso that repetitive analyses of the Daphnia-rotifer-food interactions during different seasons were possible. Rotifers and Daphnia magna showed strongly alternating population fluctuations. Daphnia appeared relatively late in the season and produced four pronounced biomass peaks between July and November. Three of the four peaks were associated with clear-water phases and reduced concentrations of sestonic carbon. The highest rotifer densities occurred before the daphnids appeared, and later in the season, the rotifer populations crashed when daphnids became abundant. Rotifer density was negatively correlated with Daphnia biomass but positively with particulate organic carbon levels. Most of the variation in rotifer abundance could be explained by fluctuations of POC levels, suggesting the existence of exploitative competition as a mechanism causing exploitative competition as a mechanism causing the inverse relationship between rotifers and Daphnids. However, a closer inspection of the time course of events indicates that mechanical interfer-ence may also be a factor and may have increased in importance as the season progressed and as the average size of daphnid individuals increased. DIEL OXYGEN CYCLE IN THREE SUBAL-PINE SWISS STREAMS.

Zurich Univ., Kilchberg (Swizerland). Hydrobio-logical-Limnological Station.

D. M. Livingstone.

No. 4, p 457-479, February 1991. 6 fig, 1 tab, 38 ref. Swiss National Science Foundation Grant

Descriptors: \*Alpine regions, \*Dissolved oxygen, \*Diurnal variation, \*Oxygen, \*Streams, \*Switzer-land, Aeration, Consumptive use, Model studies, Productivity, Respiration, Snowmelt, Water tem-

Diel variations in the oxygen concentrations of three subalpine Swiss streams are explained in terms of reaeration, production and consumption, terms of reaeration, production and consumption, based on a model employing polynomial approxi-mations over parts of the diel curve. This approach allows useful information on the oxygen regime to be obtained without the necessity of modelling all parameters over the full diel cycle. Diel curves seen in the light of the model yield much information about the relative importance of biological and physical processes occurring in the streams. During the night the oxygen deficit tends toward, and often attains, an equilibrium deficit, which is directly related to the relative importance of community respiration and reaeration. The effect of meltwater on the oxygen regime is discussed and shown to be significant, suggesting that individual meteorological events can influence the oxygen regime of a stream so strongly that any seasonal variation will be hidden. A modification of Odum's method of calculating the daily production/consumption ratios in streams to take into account the influence of stream temperature on reaeration and tion about the relative importance of biological and influence of stream temperature on reaeration and respiration coefficients is given which should result in an improvement in the results obtained. Recently it has been found that the riparian zone can contribute substantial amounts of dissolved nic carbon to a stream ecosystem. A study wa conducted in a groundwater-dominated lake in southern Sweden to determine if phosphorus can be liberated from the riparian zone and transported be hoerated from the ripariant zone and transported to the lake via shallow groundwater flow. Groundwater entering Lake Bysjon in southern Sweden is somewhat higher in specific conductance and up to 20 times higher in phosphate than the mean for the lake. This leads to elevated values of both specific conductance and phosphate in lake water within a conductance and phosphate in lake water within a 500 m long and several meter wide strip along the 500 m iong and several meter wide strip along the shore. In areas not influenced by groundwater inflow, specific conductance and phosphorus content near the shore are close to that of open lake water. High concentrations of phosphate (up to 9 mg/L PO4-P) in the inflowing groundwater originate from the riparian zone surrounding the lake. It is suggested that, over a long time, this ecotone has no suggested that, over a long time, this ecotone has accumulated phosphorus and other nutrients that were transported from the adjacent developed areas and arable land. This phosphorus is now entering the lake, probably as a result of increased decomposition of organic matter. (Agostine-PTT) W91-10931

More than a decade has passed since simple mass balance models were first used to establish target limits for phosphorus loading to the Great Lakes. Ongoing efforts to quantify both the loads to the lakes and the in-lake concentrations have resulted in a unique data set that can be used to evaluate the original application of the mass balance models. The multisegment mass balance model of Great Lakes total phosphorus developed in 1979 was used with annual phosphorus loading estimates to simulate phosphorus concentrations in 11 Great Lakes basins for the period 1974 to 1987. Compari-Lakes basins for the period 1974 to 1987. Comparison of the model results with field data collected since 1980 shows fairly good agreement, in spite of some overprediction of concentration in Lakes Superior and Ontario. A Monte Carlo technique known as regionalized sensitivity analysis was used both to identify those model parameters (including initial conditions) that were most important for producing an acceptable simulation and to examine new values for some model parameters. The model

Lakes-Group 2H

results were most sensitive to the parameters repreresults were most sensitive to the parameters repre-senting within-lake removal processes. Despite its simplicity, the Great Lakes total phosphorus model performed well and could be useful for establishing data quality objectives for phosphorus load esti-mates and surveillance programs. SIZE STRUCTURE OF PARTICULATE BIO-GENIC SILICA IN LAKE MICHIGAN. National Oceanic and Atmospheric Administra-tion, Ann Arbor, MI. Great Lakes Environmental

tion, Ann Arbor, M. Great Lakes Environmental Research Lab. D. J. Conley, and D. Scavia. Journal of Great Lakes Research JGLRDE, Vol. 17, No. 1, p 18-24, 1991. 5 fig, 22 ref.

Descriptors: \*Biochemistry, \*Diatoms, \*Lake Michigan, \*Lakes, \*Limnology, \*Silica, Cycling nutrients, Great Lakes, Microorganisms, Particle size, Particulate matter, Water chemistry.

Recent data suggest that chemical estimates of biogenic silica in the Laurentian Great Lakes include large fractions of non-living fragmented distons. Therefore, measurements of particulate biogenic silica (BSi) in different size classes (0.2-0.4 micrometers, 0.4-10 micrometers, 10-20 micrometers, and >20 micrometers) were made from April 10 micrometers. Lake Michigan 10 micrometers and page 10 micrometers and page 10 micrometers and page 10 micrometers. ters, and 20 metrointeers were made from Aprin through July 1987 in southeastern Lake Michigan to assess the importance of diatom fragments to chemical estimates of BSi. During the spring diatom bloom, the period of maximum BSi concentrations, the greatest percentage of BSi (86%) was found in the microplankton size fraction (>10 micrometers) associated with living diatoms. By contrast, following thermal stratification, when dissolved silica was depleted from epilimnetic waters, solved silica was depleted from epilimnetic waters, particles < 10 micrometers in size dominated and averaged 52% of total BSi. This fraction contained mostly fragmented diatom frustules. Our estimate of non-living diatoms is consistent with previous studies showing that, following the spring diatom bloom, 40% to 60% of total diatom abundance is non-living. Seasonal decreases in epilimnetic BSi, declining from 11.3 micromol/L in late April to an average of 1.96 micromol/L during the stratified period, were due primarily due to loss of the largest size fraction (>20 micrometers) which decreased from 76% of total BSi in April to 36% in July. BSi <10 micrometers varied by less than a creased from 76% of total 851 in April to 36% in July. BSi <a href="April to 36%" and July. BSi <a href="April to 36%" and factor of two throughout the study period, averaging 3.23 plus-or-minus 2.79 micromol/L. Particles 0.2-0.4 micrometers averaged 0.277 plus-or-minus 0.178 micromol/L. These particles are probably produced through frustule dissolution, settle slowly, and may lead to enhanced BSi recycling stees. As the of softender. rates. (Author's abstract) W91-10975

The optical properties of water have important implications with respect to heating, primary productivity, and esthetics. Optical properties of Little Sodus Bay (New York) were examined for the summer to fall interval of 1988 and contrasted to those at an adjoining Lake Ontario station. Light penetration, the angular distribution of irradiance, and the spectral quality of underwater irradiance were quantified by measurements with a Secchi were quantified by measurements with a Secchi disk, quantum sensors, and a spectroradiometer. A partitioning of light absorbing and light scattering components was developed. Light attenuation was much higher in the bay than in the lake because of the elevated levels of light absorption and scattering that prevailed in the bay, associated with the higher concentrations of phytoplankton, gelbstoff, and perhaps tripton. The enrichment with these materials also caused disparate spectral attenuation characteristics between the bay and the lake that characteristics between the bay and the lake that were manifested as strong differences in appearwere manifested as strong differences in appearance. Calcium carbonate particles were an important component of light scattering in both systems in the early part of the study. This material had a particularly striking effect on the angular distribution of irradiance in the lake. (Author's abstract)

Descriptors: \*Lakes, \*Limnology, \*Mathematical models, \*Model studies, \*Water circulation, \*Wind-driven currents, England, Finite difference methods, Numerical analysis, Shallow water.

In the management and operation of natural lakes and manmade reservoirs, hydraulic engineers are increasingly required to analyze and predict the mixing characteristics for wind-induced lake circumixing characteristics for wind-induced lake circu-lation using deterministic numerical models. The development, validation, and application of a three-dimensional deterministic numerical model of the wind-induced circulation in a shallow homoge-neous lake were examined. The governing equa-tions expressing the conservation of fluid mass and momentum were solved in the model using an implicit finite difference initial value method. Parimplicit finite difference initial value method. Parimplicit limits of interestic mittal value inclinds. The intitual rattention was paid to the representation of the bed friction, the wind shear stress, and turbulent diffusion. The model was compared with analytical solutions for three idealized flows before being calibrated and verified with field data from Esthwaite Water in Cumbria, England. The model was tested for stability and parameter sensitivity and then used to generate typical circulation pat-terns for a variety of steady-state conditions. Com-parisons with field measurements suggest that the model is better at predicting water movements in the open water than in the sheltered bays. (Author's abstract) W91-10992

After 20 yrs of above-average Great Lakes levels including the record high levels in 1985 and 1986, the Lakes experienced an unprecedented rapid drop in levels beginning in late 1986. This drop in Great Lakes levels surpassed that of the previous 20th century extreme event of 1930-31. Precipita-20th century extreme event of 1930-31. Precipitation was low from late fall of 1986 to June 1987, and again in the spring of 1988. Also, low runoff and high evaporation in the basin were experienced. While regulation of Lake Superior levels was not a factor in the decline of levels, regulation of Lake Ontario levels during this period had some impacts on that lake and downstream. Very high outflows from Lake Ontario made that the only Lake to escape setting record high levels. Over the last two years, new kinds of water level problems have surfaced throughout the watershed. Shoreline residents are unaccustomed to average or slightly residents are unaccustomed to average or slightly below average levels after 20 yrs of high levels. Recreational boats striking bottom in nearshore areas, unusable boat docking facilities and reduced water depths in the St. Lawrence River have been cause for concern. INFLUENCE OF PH ON PHOSPHATE RE-LEASE FROM SEDIMENTS.

Rijksinstituut voor Zuivering van Afvalwater, Lelystad (Netherlands). P. C. M. Boers.

P. C. M. Boers. Water Research WATRAG, Vol. 25, No. 3, p 309-311, March 1991. 3 fig, 2 tab, 9 ref.

Descriptors: \*Carbon dioxide, \*Cycling nutrients, \*Hydrogen ion concentration, \*Limnology, \*Phosphates, \*Sediment chemistry, Sediment-water nterfaces.

In eutrophic lakes, a release of phosphates from the sediments can be an important source of nutrients from the phytoplankton community. Often, the release rate is higher in the summer when tempera-tures are higher, sediment conditions are anaerobic and pH values in the water column are high. and pH values in the water column are high. Hydrogen ion concentration is believed to be an important regulating factor for the release of phos-phate from freshwater sediments. Usually this is demonstrated in laboratory experiments using intact sediment cores and pH regulation of the overlaying water by means of NaOH additions. This technique and a pH regulation technique by means of CO2-stripping were compared. The first method resulted in a 10-fold increase in release rate at pH 9.5 compared to the rate at pH 8.3. The method resulted in a 10-fold increase in release rate at pH 9.5 compared to the rate at pH 8.3. The stripping technique yielded only a doubling of the release rate at pH 9.3. Measurements of pH profiles in the sediment in experiments performed at pH 8.3 and 9.0 proved that the enhanced phosphate release when using NaOH for pH regulation is mainly an artifact caused by an increased alkalinity in the water column and the upper sediment layers, resulting from the NaOH additions. In eutrophic lakes, however, the algae can strip so much CO2 that pH values as high as 10 are possible. The results with pH 9.0 and 9.3 indicate that phosphate release rates still increase significantly with high release rates still increase significantly with high pH, although attempts to measure the natural proc-ess by NaOH addition, probably do not reflect the true process of pH increase due to CO2 depletion. IN-SITU SEDIMENT OXYGEN DEMAND IN FIVE SOUTHWESTERN U.S. LAKES. Oklahoma State Univ., Stillwater. School of Civil

Engineering.

J. N. Veenstra, and S. L. Nolen.

Water Research WATRAG, Vol. 25, No. 3, p 351-354, March 1991. 2 tab, 20 ref.

Descriptors: \*Dissolved oxygen, \*In situ tests, \*Lakes, \*Sediment chemistry, \*Sediment oxygen demand, \*Sediment-water interfaces, \*Water quality monitoring, Analytical methods, Biological oxygen demand, Chemical oxygen demand, Measuring instruments, Oxygen demand.

The rate of oxygen removal from overlying water, either by biological means or chemical oxidation of substances in the bottom material of a water body may be termed sediment oxygen demand (SOD). Reliable and accurate SOD measurement techniques and data of this potential sink for dissolved oxygen are essential for many water quality model-ing studies. In-situ SOD was measured for five

southwestern lakes from 1985 to 1988. Age, mor-phology and trophic states varied among the lakes but all were thermally stratified and had anoxic hypolimnia during summer months. SOD measure-ments were obtained with a hemispherical, sealed chamber-type benthic respirometer fitted with a submersible recirculation pump and a sensor pack-age for recording dissolved oxygen, temperature, conductivity and pH. SOD measurements were obtained at between two and four sites on most lakes. Temperature corrected values ranged from 0.34 to 9.02 g O2/sq m/d. The coefficient of variation of the SOD monitoring technique used ranged from 19% to 36%. These data significantly expand the currently accessible SOD data base for Southwestern lakes. While limited data preclude extensive statistical analysis, it appears that there may be a rough correlation between mean chlorophyll a levels and SOD. (Doyle-PTT) W91-11333

MULTICOMPONENT KINETIC ANALYSIS OF IRON SPECIATION IN HUMIC LAKE TJEU-KEMEER: COMPARISON OF FULVIC ACID FROM THE DRAINAGE BASIN AND LAKE WATER SAMPLES.

CB Research International Corp., Sidney (British

Le. E. Sojo, and H. De Haan. Environmental Science and Technology ESTHAG, Vol. 25, No. 5, p 935-939, May 1991. 5 fig, 2 tab, 25 ref.

Descriptors: \*Chemical speciation, \*Eutrophic lakes, \*Fulvic acids, \*Humic substances, \*Iron, \*Limnology, \*Water chemistry, Acidification, Catchment areas, Kinetics.

The importance of humic substances in the circulation of nutrients in humic lakes has been more often inferred than actually verified. Although laboratory studies are necessary in order to under-stand the main features of nutrient (i.e., Fe) interacstand the main reatures of nutrient (i.e., re) interac-tions with humic substances, studies including actual samples are necessary. Evidence for iron-fulvic acid complexes in natural waters is difficult to obtain due to the complexity of iron speciation. The strong tendency of iron to form hydrous oxides presents a competitive reaction against the formation of iron-fulvic acid complexes. A series formation of incineuve acid complexes. A series of experiments were conducted to study iron speciation in Lake Tjeukemeer water samples and sediments, using multicomponent kinetic analysis. The technique is based on the ligand-exchange reactions of the control tions between naturally occurring ligands (i.e., fulvic acids, OH(-), etc.) and a strong iron complexing agent (i.e., 2,4.6-ti(2-yridyl)s-triazine (TPTZ)). Guggenheim's method of kinetic analysis was then used to provide estimates of rate con-stants and initial species concentrations. The kinet-ic data obtained from the experiments revealed that iron was distributed among iron-fulvates and polymeric hydrous oxide species. The results of the study provided support for the use of multi-component kinetic analysis to determine iron speciation in natural water samples. In addition, this technique can be used to monitor changes in iron speciation due to seasonal variations and changes in water quality. (Korn-PTT) W91-11339

DENDROGEOMORPHIC APPROACH TO MEASUREMENT OF SEDIMENTATION IN A FORESTED WETLAND, BLACK SWAMP, AR-KANSAS.

Lakes-Group 2H

C. R. Hupp, and E. E. Morris. Wetlands, Vol. 10, No. 1, p 107-124, 1990. 7 fig, 2 tab, 42 ref.

Descriptors: \*Black Swamp, \*Dendrochronology, \*Dendrogeomorphology, \*Geomorphology, \*Sedimentation, \*Wetlands, Arkansas, Baldcypress trees, Cache River, Data acquisition, Forest wetlands, Sedimentation rates, Swamps, Tupelo trees.

Dendrogeomorphic techniques were used to describe and interpret the spatial and temporal patterns of sedimentation in the Black Swamp, located along the Cache River in eastern Arkansas. At 30 sites along four transects, 148 trees were examined for depth of sediment accretion and cored for age sites atong from transects, I we trees were examined for depth of sediment accretion and cored for age determination. Tree ring and geomorphic analyses indicated that mean sedimentation rates were significantly related to site elevation, topographic position, and the distribution of tupelo gum and bald cypress. Maximum mean rates of sedimentation, as high as 0.60 cm/hr, generally occurred in sloughs, areas low in elevation, and where tupelo gum and bald cypress grow. Mean sedimentation rate appeared to have a negative exponential relation with increasing elevation. Tree age class data indicated a significant increase in sedimentation rate about 1945, from a mean at or below 0.01 cm/yr to a mean of 0.28 cm/yr for the past 19 years. Dendrogeomorphic techniques provide valid estimates of sedimentation rate and allow for the integration of decades of depositional processes in the rate calculations. decades of depositional processes in the rate calculation. PHOSPHORUS LOSSES FROM THE EPILIM-

PHOSPHORUS LOSSES FROM THE EFILIM-NION IN RIMOV RESERVOIR. Ceskoslovenska Akademie Ved, Ceske Budejovice. Inst. of Landscape Ecology.

P. Porcalova. Internationale Revue der Gesamten Hydrobiologie IGHYAZ, Vol. 75, No. 3, p 273-279, 1990. 2 fig, 3

Descriptors: \*Epilimnion, \*Eutrophication, \*Lim-nology, \*Phosphorus, \*Rimov Reservoir, \*Sedi-mentation rates, Biomass, Czechoslovakia, Eutro-phic lakes, Lake sediments, Phytoplankton, Sea-sonal variation, Sedimentation, Seston, Traps, Water chemistry.

Main components of the phosphorus budget of a reservoir are input, output, and sedimentation. Ex-ternal loading and phosphorus removal from the water column by sedimentation are crucial for reservoir phosphorus content. During eutrophica-tion processes, bottom sediments accumulate large quantities of phosphorus, which may be released into water under certain conditions. This release of mto water under certain continuous. In stelease of P from sediments and subsequent transport upward through the hypolimnion plays an important role in the development of the reservoir's trophic status. The amount of deposits accumulated during eutrophication is important, particularly in lake or reservoir restoration. Sediment traps were placed at three depths near the dam of the Rimov reservations of the Rimov reservations are the dam of the Rimov reservations. at three depths near the dam of the Rimov reservoir, Czechoslovakia, and at the bottom along the reservoir from April 1986 to April 1987. The highest amounts of phosphorus in trapped material was obtained during the fall turnover in the epilimnion, and near the bottom in both spring periods. During the growing period, variations in dry weight and total phosphorus in settling seston were related to changes of phytoplankton biomass in the trophogenic layer. The flux of settling phosphorus insettling seston was higher in the hypolimnion than in the epilimnion throughout the year. During summer stratification the variability of dry weight and phosphorus sedimentation followed changes in phytoplankton biomass in the epilimnion. Sedimentation measurements along the Rimov Reservoir showed that half of the phosphorus input was deposited within the first 3 km of the length of the reservoir. (Medina-PTT)

PROCESSING OF LEAVES OF TREES AND AQUATIC MACROPHYTES IN THE NETWORK OF THE RIVER RHONE.

Mohamed-1 Univ., Oujda (Morocco). Dept. de

H. Chergui, and E. Pattee. Internationale Revue der Gesamten Hydrobiologie IGHYAZ, Vol. 75, No. 3, p 281-302, 1990. 8 fig, 2

Descriptors: \*Aquatic life, \*Decomposing organic matter, \*Detritus, \*Leaves, \*Macrophytes, \*Mi-crobial degradation, \*Rhone River, Alder trees, Aquatic fungi, Ecosystems, Literature review, Litter, Organic matter, Oxygen, Phragmites, Poplar trees, Willow trees.

The decomposition of vegetable particulate organin actecomposition of vegetable particular organ-ic matter is one of the major inputs of energy to aquatic ecosystems. A study was made on the processing of these inputs to record the availability of organic matter at different periods of the year. Dead leaves of three species of trees, alder, poplar Dead leaves of three species of trees, aider, poplar and willow, and two aquatic macrophytes. Potamogeton and Phragmites, were enclosed in coarse mesh (10 mm) and fine mesh (0.3 mm) plastic bags and exposed in two contrasted backwaters of the Rhone River (southeastern France). One was connected with a channel of the river at its downstream end, and the other on a completely closed oxbow lake. Regardless of the biotope, the break-down rate of leaves ranked in the following order: submerged and floating Potamogeton > aider and poplar > willow and emerging Phragmites. In coarse mesh bags, colonization of the leaves by invertebrates occurred in the same order. Shreders appeared first, with predators and collectors inverterates occurred in the same order. Shred-ders appeared first, with predators and collectors later. The time lag before colonization indicated that microbial conditioning of the leaves also pro-ceeded in the same order. The natural date of senescence and eventual immersion of the leaves sensether and eventual intersion of the leaves provided consumable allochthonous and autochth-onous organic matter to the river system through-out the year, from summer to the following spring. Comparison with earlier studies showed the exist-Comparison with earlier studies showed the existence of a transverse gradient in the fluvial network. Under the influence of fungal and invertebrate colonization, breakdown velocity was highest in the channel, less in the half-closed side arm, and lowest in the completely enclosed lake. These results suggest that this gradient was due initially to the indirect influence of water motion and oxygen availability on leaf colonization by Hyphomycetes. (Medina-PTT)

NATURAL PHOSPHATE SOURCE FOR LAKE WACCAMAW, NORTH CAROLINA, USA. North Carolina Univ. at Wilmington. Dept. of

L. B. Cahoon, J. R. Kucklick, and J. C. Stager. Internationale Revue der Gesamten Hydrobiologie IGHYAZ, Vol. 75, No. 3, p 339-351, 1990. 3 fig, 4 tab, 32 ref.

Descriptors: \*Eutrophication, \*Lake Waccamaw, \*Limnology, \*Phosphates, Environmental chemistry, Eutrophic lakes, Lake management, Lake morphometry, Lake sediments, Limestone, North Carolina, Pollutant identification, Water chemistry, Water Chem Weathering.

Lake Waccamaw is one of the largest natural lakes in North Carolina and the largest of the Carolina Bay Lakes, a distinctive morphometric type with a shallow, elliptical basin. A limestone outcrop along

its north shore was found to contain 0.1% phosphate by weight. Weathering processes have probably driven steady inputs of phosphate from this source throughout the lake's history, accounting for its near-eutrophic state. The sediments of the lake are enriched with phosphate, particularly in the littoral zone near the outcrop. Chemical and biological processes apparently remove phosphate from solution rapidly, making detection of a soluble phosphate signal near the outcrop difficult. Management of nutrient inputs and water quality in Lake Waccamaw requires consideration of the Management of nutrient inputs and water quanty in Lake Waccamaw requires consideration of the effects of this in-lake source of phosphate. Other sources of phosphate, particularly in the lake drainage basin, may be less important than previously thought. (Author's abstract)

VARIATION IN THE ACIDITY OF GROUND AND SURFACE WATERS IN NORTHERN IRE-LAND.

Departm ent of Agriculture for Northern Ireland, Antrim. Freshwater Biological Investigation Unit. C. Jordan, and I. J. Enlander.

Internationale Revue der Gesamten Hydrobiologie IGHYAZ, Vol. 75, No. 3, p 379-401, 1990. 9 fig, 5 tab, 51 ref.

Descriptors: "Acid rain, "Acidification, "Acidity, "Aluminum, "Groundwater chemistry, "Northern Ireland, "Water pollution effects, Acidic lakes, Drinking water, Environmental chemistry, Eutrophication, Geology, Hardness, Hydrogen ion concentration, Maps, Surface water, Trout, Water

It is known that Northern Ireland experiences deposition levels of hydrogen and sulfate ions which are high enough to acidify both surface and groundwaters in some upland areas where the soils have poor buffering capacities. Existing data on both surface and groundwater from around Northern Ireland were mapped using SYMAP techniques into one of 5 classes representing waters ranging from those which are permanently or occasionally acid (SYMAP class 1), to those with high enough buffering capacity that they never become acid under current levels of acid deposition (SYMAP class 2), and to those that are never likely to suffer from acidification (SYMAP class 3). The distribution of each class of water was likely to suffer from acidification (SYMAP class 3-5). The distribution of each class of water was explained on the basis of the regional geology and pedology of Northern Ireland and the ability of soils and rocks to neutralize incoming acidity. Aluminium levels in those areas identified as being vulnerable to acidification (the Mourne and Sperin mountains and the Glens of Antrium) were found to be between 72 and 241 microg/L total aluminum of which most was in its most toxic, labile form at the pH's of the waters concerned. However, a survey of the Silent Valley in the Mourne mountains, where the pH was known to Mourne mountains, where the pH was known to vary between 4.5 and 5.8, and where the labile aluminium concentration was 230 microg/L, showed that this public supply reservoir sustained showed that this public supply reservoir sustained a small population of apparently healthy brown trout in the age range of 1-4+. It was considered that sudden changes in pH or aluminium concentrations due to acid rain (pH = 3.8) in the vulnerable areas identified in this study posed the greatest threat to the survival of fish stocks in these areas. The largest lakes in the Province, Loughs Neagh and Erne, are not susceptible to acidification and have very low aluminium concentrations, all of which is non-labile. (Medina-PTT)

PROXIMATE COMPOSITION AND NUTRI-ENT ELEMENTS IN THE UNUSUAL ALGAL JELLIES OF LAKE OGUTA IN SOUTHERN

Port Harcourt Univ. (Nigeria). C. Nwadiaro, and P. Idabor. Internationale Revue der Gesamten Hydrobiologie IGHYAZ, Vol. 75, No. 3, p 413-420, 1990. 2 tab,

# Group 2H-Lakes

genesis, Drinking water, Limnology, Magnesium, Nigeria, Potassium, Seasonal variation, Sodium, Species composition, Water quality.

Unusual planktonic algal communities, conveniently called algal jellies, are not common in tropical lakes, but have been reported in Japan and Northern Cameroon. There is a high similarity in the consistency and gross taxonomy of these Japanese and Nigerian algal formations. The proximate composition, nutrient and trace elements of algal jellies samples from Lake Oguta in Southern Nigeria were analyzed to provide guidelines for their utilization and management. Samples were obtained in the rainy (flood) and dry seasons. Species identification revealed mostly blue green algae (Microystis, Anabaena, Chroococcus) with some green algae (Spirogyra) and diatoms (Navicula) that were epiphytic on the mucous jellies of the blue-Unusual planktonic algal communities, convenientalgae (Spirogyra) and diatoms (Navicula) that were epiphytic on the mucous jellies of the bluegreen algae. Water content was high (98.2% mean, range 97.5-95.5%) Ash, protein and fat mean values were 41.7%, 16.9%, and 2.0%. Phosphorus and nitrogen levels were high, and the major cation order of dominance was Ca > K > Mg > Na, differing from that of the lake water. Macronutrient concentrations increased during the rainy season, concentratios of micronutrients decreased. seasonal changes in ionic concentrations were at-tributed to diagenesis of endogenic minerals and not to anthropogenic factors. The economic value of these jellies include its possible use as a fertilizer, compost and mulching material for agriculture, and, a protein source for fish and livestock feeds. The use of chemicals (algicides) to control algal growth was not practical in this lake due to the dependence of the local community on the lake as a direct source of drinking water. TEMPERATURES LETHAL TO SALVINIA

MOLESTA MITCHELL.
Commonwealth Scientific and Industrial Research Organization, Indooroopilly (Australia). Div. of Entomology.

J. B. Whiteman, and P. M. Room. Aquatic Botany AQBODS, Vol. 40, No. 1, p 27-35, April 1991. 4 tab, 17 ref.

Descriptors: \*Aquatic weeds, \*Biocontrol, \*Ferns, \*Salvinia, \*Survival, \*Temperature effects, Cacti, Mortality, Nutrients, Submerged aquatic plants,

A laboratory study was undertaken to determine the effects of extreme temperatures on the survival of an aquatic weed, the Brazilian floating fern Salvinia molesta. Large phenets of S. molesta, each consisting of at least 12 ramets, were grown at different temperatures and durations of exposure at five different nutrient levels. At low temperatures, phenets survived all combinations of temperature, duration, and nutrient level, except for the -6 C setting, zero nutrients for 7 and 16 h, and high nutrients for 16 h. At high temperatures, there was nutrients for 16 h. At high temperatures, there was no survival at 6 and 16 h at the 48 C setting, and at 4 and 6 h at the 50 C setting. Examination of the temperatures actually experienced suggested that death occurred after plants had been exposed to water temperatures < -3 C for a few hours (when tice probably forms on the plant) or > 43 C for more than a few hours. This is within the ranges reported for some submerged aquatic plants and shade-inhabiting herbs. The upper temperature limit is low compared with the 50-55 C limit reported for herbs growing in the sun and 70-74 C limit is low compared with the 50-55 C limit reported for herbs growing in the sun and 70-74 C reported for cacti. Phenets appeared to survive low temperatures better when they were supplied with nutrients, but the effect was small. At high temperatures, greater survival of high-nutrient phenets at 40 C was contradicted by greater sur-vival of zero-nutrient phenets at 50 C. Experimental conditions were unrealistic in that plants re-ceived no light during exposures and did not experience gradual changes leading to and from exposure temperatures. (Doria-PTT) W91-11450

IMPACT OF CARBON DIOXIDE AND AMMO-

IMPACT OF CARBON DIVAIDE AND AMMO-NIUM ON THE GROWTH OF SUBMERGED SPHAGNUM CUSPIDATUM. Katholieke Univ. Nijmegen (Netherlands). Dept. of Aquatic Ecology and Biogeology. B. G. P. Paffen, and J. G. M. Roelofs. Aquatic Botany AQBODS, Vol. 40, No. 1, p 61-71, April 1991. 3 fig, 6 tab, 23 ref.

Descriptors: \*Ammonium, \*Carbon dioxide, \*Land use, \*Peat bogs, \*Peat harvesting, \*Plant growth, \*Plant physiology, \*Sphagnum, \*Sub-merged aquatic plants, \*Wetlands, Air pollution, Biomass, Mortality, Spectrophotometry, Statistical analysis, The Netherlands.

Plants of Sphagnum cuspidatum were collected from the peatland 'Groote Peel' (The Netherlands) and placed in glass containers to study the influand placed in glass containers to study the influence of carbon dioxide and ammonium on their growth. Results showed that at any CO2 level below 750 micromol/L, plants were in bad condition or dead. At 750 micromol/L the plants were fragile, but at 1,000 micromol/L most plants were very vital and floating, independent of the ammonium concentration of the medium. The percentage of living classification of the medium. of living plants after 12 weeks of cultivation was also the highest at 1,000 micromol CO2/L, independent of the amnonium level. The growth in length was also significantly higher at high CO2 levels than at the lowest CO2 level. The highest growth in length was found at the highest CO2 and ammonium concentration, but the differences between the various ammonium concentrations were not significant (Wilcoxon test). After a cultiwere not significant (Wilcoxon test). After a culti-vation period of 12 weeks the biomass decreased from initial biomass levels only at a CO2 level of 250 micromol/L (-19). The increase in biomass was greatest at a CO2 concentration of 1,000 mi-cromol/L (+18%). At high CO2 levels, biomass increased at all levels of mimonium. Element concentrations were generally higher after the culture period. It is concluded that the CO2 concentration of the water layer is of vital importance for the growth of submerged S. cuspidatum, at least 750 micromol CO2/L being necessary for optimum growth. Ammonium concentration is less important. (Doria-PTT) W91-11452

Descriptors: \*Dating, \*Geography, \*Kleiner Barsch-See, \*Limnology, \*Paleolimnology, \*Paly-nology, \*Pollen, Color, Evaporation, Germany, Glaciation, Hydrologic budget, Ice, Lakes, Mor-aines, Profiles, Rainfall, Sediments, Water level.

Lake Kleiner Barsch-See, a kettlehole-like basin Lake Kienier barkin-see, a kettenlori-ike usain situated within an undrained hollow between the terminal moraines of the Furstenberger and Frank-furter Staffel (Potsdam District, Germany) was formed after the Weichselian stage of the last glaciation. A small oval depression first originated from a melting dead-ice block, eventually creating a lake which now has an area of about 0.3 ha. Its actual water level is 60 m above sea level (asl); the moraines reach 65-75 m asl. Surface inflows and effluents are absent. Rainfall and evaporation compensate each other. Sediment cores of about 6 m pensate each other. Seathneth cores or about of more taken from ice using a modified Livingstone sediment sampler. The sediment color ranged from black to olive brown and olive green with the exception of a small whitish core around 936 cm below water level. This core is identical to the so-called Laach Tephra, dated more than 11,000 years BP. The pollen profile showed a gap between 10,000 and 8,000 years BP. It was concluded that the lake was formed more than 12,000 years BP. (Author's abstract) W91-11514

HISTORY OF CLADOCERA IN THE KLEINER HISTORY OF CLADOCERA IN THE ALEINER
BARSCH-SEE, AN ACIDIC, CALCIUM-POOR,

Descriptors: \*Acid lakes, \*Acid rain, \*Calcium, \*Eutrophication, \*Kleiner Barsch-See, \*Lake acidification, \*Limnology, \*Paleolimnology, \*Waterfleas, \*Wetlands, Acidity, Agriculture, Ecosystems, Germany, Glaciation, History, Hydrogen ion concentration, Lake sediments, Mosses, Plankton, Population dynamics, Species composition, Species diversity, Water level.

The distribution of subfossil remains of Cladocera a sediment core from the acid Kleiner Barsch-See (northern East Germany) was examined. A total of 35 species was recorded: 10 non-chydorids and 25 chydorids. Analysis of the cladoceran disand 25 chydorids. Analysis of the cladoceran dis-tribution was based on dominance of the species diversity and equitability. The developmental his-tory of the lake can be divided into three phases. The first period, during late glacial time, was char-acterized by a well developed plankton fauna, dominated by Bosmina langirostris. During the transition from late glacial to postglacial time, the lake changed by in-filling the basin. Chydorids increased in abundance, primary production shifted from phytolankton to macrophytes. The last from phytoplankton to macrophytes. The last phase spaned all of postglacial time, and was charphase spaned all of postglacial time, and was characterized by an increasing abundance of macrophytes (especially water mosses) decreasing pH and calcium content of the water, and a cumulative deposition of organic sediment in the shallow pond. The process of acidification was dependent on the lake level, with increasing acidification during wet periods and decreasing acidification during dry periods. Species diversity decreased with increasing acidity. The reappearance of B. longirostris in postglacial time indicate eutrophication of the water as a result of increased agricultural development during the Bronze Age and early al development during the Bronze Age and early Middle Ages. A core (620 cm) from the sediment of a small acid forest lake (Kleiner Barsch-See, northern East Germany), was investigated for its content of subfossil shells of protozoa, and was found to contain 31 species of Testacea and 1 ciliate (Codonella cratera). The most abundant species was Centropyxis aculeata; durability of shells was poor. X-ray microanalysis to compare the chemical composition of subfossil and recent shells yielded contradictory results; a discontinuous size polymorphism of shells was observed for a few species. Recent dictory results; a discontinuous size polymorphism of shells was observed for a few species. Recent and subfossil populations were compared, with shells of Difflugia oblonga and D. globulosa showing favored size classes. Recent and subfossil size peaks had an insignificant shift. Centropyxis aculeata (and therefore C. hirsuta) was found to be too variable in size to be useful in the study. However, in the course of development of the lake, C. aculeata indicated only one main size class surroundleata indicated only one main size class, surrounded by subsidiary classes. Recently investigated populations of C. aculeata did not possess a fapopulations of c. acuteata un not possess a la-vored size class. In the course of development of the lake, C. aculeata also formed temporal races of short duration. Other interesting species found in the area included C. nauwercki and D. kabylica. Etlle Therapie. S. J. Casper, and W. Scheffler. Limnologica LMNOA8, Vol. 21, No. 1, p 147-155, October 1990. 3 fig. 1 tab, 16 ref.

Descriptors: \*Acidification, \*Diatoms, \*Glacia-tion, \*Kleiner Barsch-See, \*Lake acidification, \*Paleolimnology, \*Stratigraphy, Acid lakes, Acidic lakes, Germany, History, Hydrogen ion concentration, Peat, Population dynamics, Silica, Water level, Water level fluctuations.

Post-deglaciation changes in lake water level and pH were investigated in the Kleiner Barsch-See, a small acid forest lake in East Germany, by means small acid forest lake in East Germany, by means of diatom stratigraphy. Diatom development in the lake showed two distinct phases during the late glacial and postglacial period. Diatoms found in the lowermost samples (diatom zones 1 and 2; Late glacial) indicate a slightly alkaline to circumneutral state of the juvenile lake, along with with a well developed pelagic zone and a fairly high water level. An increased dominance of Fragilaria spp. in cone 2; indicates the initial lowering of the water. level. An increased dominance of Fragilaria spp. in zone 2 indicates the initial lowering of the water level. A relatively abrupt change in material at about 880 cm may be due to the lowering of the water level when overgrowth of the lake led to peat formation and acidification, a process which lasted through the whole Postglacial period. Extremely small numbers of diatoms were found. The topmost 9 cm of the core reflect a better (aerial) nutrient supply and possible acidification during the past 20 years. The two main phases in diatom development described are well known from investigations of similar lakes in northern Europe and trigations of similar lakes in northern Europe and America, and are in good agreement with results from biosilica analysis. Descriptors: \*Acid lakes, \*Chemical composition, \*Kleiner Barsch-See, \*Lake sediments, \*Limnology, \*Paleolimnology, \*Stratigraphy, Bogs, Calcium carbonate, Carbon, Environmental chemistry, Germany, Groundwater, Hardness, Hydrogen, Iron, Litter, Manganese, Moisture content, Nitrogen, Phosphorus, Silica.

Stratigraphic investigation of the Kleiner Barsch-See, a small acid forest lake in Germany, revealed two distinct series of Late Glacial and Postglacial sediments. The lower, older sediments (8500-950 cm beneath the water surface) have a low water content (72%) and up to 12% CaCO3, and are rich cm oeneant me water surface; have a low water content (72%) and up to 12% CaCO3, and are rich in iron (14%), manganese (0.6%), and phosphorus (1.05%); biosilica content averaged 20 mg Si/g dry residue (geogenic phase). The layer above this one has a high water content (96.4%), is carbonate-free and poor in Fe (0.23%), Mn (0.041%), P (0.05%), and biosilica (0.8 mg Si/g dry residue). The C/N ratio averages 12.5, indicating Dy-sediment (ombrogenic phase). The lower layers (S2) are autochthonous sediments of a postglacial hard-water lake enriched with elements (Fe, Mn, P, and biosilica) transported from the drainage area. As the waters became sealed off from groundwater and the supply of elements diminished, the water became electrolyte-poor, and the character and chamged. The upper layers (S1) are composed of biogenic peaty plant material of predominantly allochthonous origin from the shore and litter from the surrounding woods. (Doria-PTT) the surrounding woods. Descriptors: \*Concepcion, \*Fish, \*Species composition, \*Stagnant water, Cattle, Ecological distribution, Floating plants, Limnology, Macrophytes, Paraguay, Population dynamics, Shallow water.

Zoological and limnological studies were carried Zoological and limnological studies were carried out in one shallow lake and 4 perennating pools (known as tajamares) near Concepcion, Paraguay. Eighteen species belonging to 9 families were netted. The largest number of species (13) were found in the shallow lake, and the smallest (3) from pool number 3, which has steep banks and a limited quality of macrophytes. The pool of the greatest number of species (7) was pool number 2, which is protected from cattle damage and has extensive stands of floating plants. No one species was found in all bodies of water studied. The most widely distributed were Pyrrhulina brevis and Cichlasoma in all bodies of water studied. The most widerly distributed were Pyrrhulian brevis and Cichlasoma dimerus, each of which was found in 4 of the 5 water bodies. Of the 13 species found in the shallow lake, 8 were not found in the pools. (Dorialous Lake, 8 were not found in the pools.) PTT) W91-11523

LOCAL AND SEASONAL VARIATION OF THE EPIPELIC ALGAE IN SAMARRA IMPOUNDMENT, IRAQ.

Iraq Atomic Energy Commission, Baghdad. A. W. Sabri.

Limnologica LMNOA8, Vol. 21, No. 1, p 275-279, October 1990. 2 fig, 3 tab, 25 ref.

Descriptors: \*Algal growth, \*Limnology, \*Reservoirs, \*Samarra Reservoir, \*Species composition, Algal blooms, Benthic environment, Chlorophyll a, Cyanophyta, Diatoms, Iraq, Limiting nutrients, Phosphates, Phosphorus, Population density, Seasonal variation, Silicates.

The epipelic algal populations in the Samarra Impoundment (Iraq) were studied seasonally during 1987 and 1988. A total of 78 taxa were identified, 1987 and 1988. A total of 78 taxa were identified, with diatoms the dominant group represented by 73 taxa, mostly of the pennate type. Summer and autumn were found to be the best growth season when most taxa were present. Cyclotella ocellata was the dominant species (in quantity) in the pool region, while no clear dominance appeared at other stations. Chlorophyta and Myxophyta (Cyanophyta) were occasionally recorded in low densities only during summer and autumn. Phosphate ranged from 0.003 to 0.039 mg/L. Lower values were reported during winter and spring phate ranged from 0.003 to 0.039 mg/L. Lower values were reported during winter and spring indicating the possibility that phosphorus is a limiting factor for algal growth. Silicates were recorded in concentrations sufficient for algal growth (>1 mg/L), however, during winter there values were very low at one station. especially during winter. This agrees with the known general sequence of silicate depletion after algal bloom. The content of sediment as estimated quence of sincate depiction after again bloom. In organic matter contents of sediment, as estimated in April, had values ranging from 116.72 to 190.89 mg/g. The maximum chlorophyll a content was 3.42 mg/m, correlating closely with mean total cell counts. This reflect the fact that diatoms were the main contributors to chlorophyll a at all of the stations. It was concluded that the recruitment of planktonic species into benthic habitats is an important factor affecting floral composition in epipelic algal communities. (Doria-PTT)

IMPACT OF PHYSICO-CHEMICAL COM-PLEXES ON PLANKTON DENSITY IN DHIR BEEL OF ASSAM.

Gauhati Univ. (India). Dept. of Zoology. Galinari Ginv., Initials, pept. of 2000gy. Y. S. Yavada, and S. C. Dey. Limnologica LMNOA8, Vol. 21, No. 1, p 287-292, October 1990. 1 fig, 10 tab, 19 ref.

Descriptors: \*Dhir Beel (lake), \*Lake ecology, \*Limnology, \*Plankton, \*Population density, \*Water properties, Ammonia, Calcium, Chemical properties, Dissolved oxygen, Dissolved solids, Hydrogen ion concentration, India, Iron, Nitrogen, Phosphorus, Physical properties, Regression analysis, Seasonal variation, Silicates, Statistical analysis.

Multivariate analysis was used to study the impact of physical and chemical conditions on plankton density in Dhir Beel, a riverine lake in Assam (India). It was found that 10 variables explained India). It was found that 10 variables explained 61% of the variation when plankton densities, at different levels, are not considered separately. However, the multiple correlation coefficient (R) increased significantly when levels were treated separately (17 variables accounted for the 94% variation at the surface, while 8 explained the 67% variation at the bottom). These findings, indicate that multiple variation interaction can better explain the variation in plankton density at separate levels. The regression equation (RE) of all three analyses showed that dissolved oxygen (surface and bottom), ammonia-nitrogen (surface), SiO2 (bottom), and month (July) correlate best with plankton density, giving and exponential fit. pH (bottom), iron (bottom), phosphorus (bottom), and

#### Group 2H-Lakes

level (bottom level) were significant when levels are combined; Fe (bottom), Ca (surface), P (bottom), SiO2 (surface), dissolved organic matter (surface), month (February to July), and horizontal sector are significant at the surface level; and pH (surface) and P (surface) at the bottom level. The contraces and resultance at the contoin even the appearance of level and sector in the combined RE indicates a variation in plankton density on both vertical and horizontal planes in the Beel. Results justify the deletion of insignificant factors from physicochemical studies to increase the efficiency of data collection. (Doria-PTT)

SEASONAL VARIATIONS AND RELATION-SHIPS OF DIFFERENT PHYSICO-CHEMICAL CHARACTERISTICS IN NEWLY MADE TAWA

Government Home Science Coll., Hoshangabad Government Home Science Coll., Hosnangabad (India). Dept. of Zoology. S. Singhal, G. M. A. Ramani, and U. S. Gupta. Limnologica LMNOA8, Vol. 21, No. 1, p 293-301, October 1990. 17 fig, 2 tab, 30 ref.

Descriptors: \*India, \*Limnology, \*Reservoirs, \*Water properties, Alkalinity, Analysis of variance, Bicarbonates, Calcium, Carbon dioxide, Carbonates, Chemical properties, Chlorides, Dissolved oxygen, Hardness, Hydrogen ion concentration, Littoral zone, Nitrates, Oligotrophy, Phosphates, Physical properties, Seasonal variation, Statistical analysis, Sulfates, Temperature, Transparency, Water temperature

Water temperature.

Montly and seasonal variations of different physicochemical characteristics in the Tawa Reservoir, Madhya Pradesh, India, were evaluated at three stations (2 littoral and 1 limnetic) with three levels (surface, middle, and bottom). Correlation coefficients were calculated between 17 pairs of varia-bles to construct correlation matrices. The minimum value of Secchi transparency was observed during the rainy season. A direct relationship was found between air and water temperature, and between pH and water temperature during the between pH and water temperature during the summer season, the last relationship due to the the behavior of phytoplanktonic gross primary productivity, Generally, water in the Tawa Reservoir remained alkaline because of the abundance of buffering substances (rain water and carbonates). High values of free CO2 were recorded in the monsoon period, attributable to the decreased availability of sunlight. High O2 concentrations were recorded in late winter and early summer, while low values were recorded in the rainy while low values were recorded in the rainy season. The low values of O2 during this season may be due to a heavy influx of waters, resulting in poor photosynthesis. Dissolved oxygen (DO) was positively correlated with pH during rainy and winter seasons, and negatively correlated with bicarbonates. The analysis of variance for chloride carbonates. The analysis of variance for chloride was significant with season; chloride concentration varied between 12-40 ppm, showing the oligotrophic nature of the reservoir. Sulfate values were recorded between 19 and 5.7 ppm. No clear seasonal trend was found, although sulfates were positively correlated with phosphate during the rainy and winter season. Values of phosphate ranged between a low of 0.060 ppm and a high of 0.098 ppm. The values remained nearly constant throughout all of the seasons. Values of nitrate during rains were higher than in other seasons, due primarily to the addition of nitrates into the reservoir from runoff water. (Doria-PTT) W91-11528 W91-11528

HABITAT USE BY AN ASSEMBLAGE OF FISH IN A LARGE WARMWATER STREAM. Virginia Polytechnic Inst. and State Univ., Blacks-burg. Dept. of Fisheries and Wildlife Sciences.

Shallow water, Species composition, West Virgin-

The New River is a sixth-order warmwater stream in southern West Virginia. Habitat use patterns were examined in a fish assemblage in a 60-400 m wide reach of the river. Fish species and life stage composition and densities differed among habitat composition and densities differed among national types, and five habitat-use guilds were proposed: edge pool, middle pool, edge channel, riffle, and generalist. Larger centrarchids used deep habitats with slow velocities, whereas young centrarchids used shallower habitat. Juvenile and adult smallmouth bass Micropterus dolomieui were nearly ubiquitous in the habitats of the study area, although densities were highest among snags. Min-nows and darters used shallower areas, but the range of velocity used differed among species and life stages. Vegetated and channel edge habitats served as nursery areas. Total fish densities were highest in edge pool, backwaters, snags, edge rifles, and rifles. Nearshore, structurally complex habitats seem important in influencing the assemblage structure of fishes of large streams. Proposed peaking power operations at Bluestone Dam may affect standing stocks of benthic macroinvertebrates in the New River through erosion of macrophytes. The productivity of many fish could also be adversely affected because of the reduction of macroinvertebrate prey and the loss of emergent and submerged vegetation. Finally, the association range of velocity used differed among species and macroinverteorate prey and the loss of emergent and submerged vegetation. Finally, the association of the sport fish with the rare snag habitats sug-gests the potential value of habitat improvement with natural materials. (Author's abstract) W91-11533

DISTRIBUTION, HABITAT USE, AND GROWTH OF AGE-0 COLORADO SQUAW-FISH IN THE GREEN RIVER BASIN, COLO-RADO AND UTAH.
Fish and Wildlife Service, Vernal, UT.

Transactions of the American Fisheries Society TAFSAI, Vol. 120, No. 1, p 79-89, January 1991. 3 fig. 5 tab, 17 ref.

Descriptors: \*Aquatic habitats, \*Ecological distri-bution, \*Fish, \*Growth, \*Squawfish, \*Stream fish-eries, Colorado, Flow, Green River Basin, Growth stages, Larval growth stage, Population density, Sampling, Seasonal variation, Shores, Survival, Temperature, Turbidity, Utah, Water depth.

Age-0 Colorado squawfish Ptychocheilus lucius (N=11,379) were captured as larvae and postlarvae in drift nets and seines in the Green and Yampa rivers from 1979 to 1988. Larvae were captured in drift nets (N=601) for 2-6 weeks in June and July. Small postlarvae (N=3,079) were captured by seining shoreline habitats in July and August. In September and October, postlarvae were most abundant (N=6.459) in low-gradient reaches of the abundant (N=6,459) in low-gradient reaches of the Green River. Catch data indicated that the postlarvae moved from the Yampa and Green river spawning areas and were concentrated about 150 km downstream by autumn of each year. Spring sampling indicated that young fish (N=1,240) overwintered in areas occupied the previous autumn. Postlarvae captured in the Green River autumn. Postlarvae captured in the Green River (N=5,043) most frequently occupied shoreline embayments (backwaters) that were relatively warm (mean, 17.0 C), deep (mean, 38 cm), large (mean, 826 sq m), and turbid. Abundance and size of young Colorado squawfish in the Green River were inversely correlated with high summer and autumn flows, which inundated nursery habitats. Seine catches of young squawfish in 4 years of sampling the upper and lower Green River in autumn and the following spring were not reliable in assessing overwintering mortality of age-0 Colorado squawfish, presumably due to differences in capture vulnerability between seasons. Survival of small fish in spring indicated their tolerance of prevailing winter conditions. (Author's abstract) W91-11534

MODELS OF SEASONAL GROWTH OF THE EQUATORIAL CARP LABEO DUSSUMIERI IN RESPONSE TO THE RIVER FLOOD CYCLE.

Colombo Univ. (Sri Lanka). Dept. of Zoology. M. A. K. Smith.

Environmental Biology of Fishes EBFID3, Vol. 31, No. 2, p 157-170, June 1991. 8 fig, 5 tab, 42 ref.

Descriptors: "Model studies, "Floods, "Stream fisheries, "River flow, "Carp, "Seasonal variation, "Mahaweli Ganga, Sri Lanka, Monsoon, Flood peak, Fish growth, Temperature, Hydrogen ion concentration, Light intensity, Conductivity,

The phenology of Labeo dussumieri, an omnivorous carp common to South Asia, was investigated in a population inhabiting a flood plain anabranch of the Mahaweli Ganga, Sri Lanka. The Mahaweli Ganga exhibited a bimodal discharge pattern typical of many equatorial rivers, with a minor peak during the S.W. monsoon and a major peak during the N.E. Monsoon. Seasonal changes in several losts variables water measured in a attempt to lotic variables were measured in an attempt to correlate changes in environmental conditions to reproduction and growth in L. dussumieri. The onset of gonad recrudescence and spawning were onset of gonad recrudescence and spawning were synchronized with the increased river discharge during the S.W. and N.E. monsoons: gonad development followed one monsoonal discharge peak and spawning took place at the beginning of the other. Most fish spawned at the beginning of the major discharge peak in October and November, following the September dry season. Growth was shown to be seasonal, exhibiting an annual bimodal nattern with peaks coincident with S.W. and N.E. shown to be seasonal, exhibiting an annual bimodal pattern with peaks coincident with S.W. and N.E. monsoonal rains. Seasonal changes in growth were expressed by two models in terms of: (1) change of somatic weight or fork length with time, and (2) change of specific growth rate in response to river discharge, modified by somatic weight. Gonad recrudescence and spawning stress did not appear to influence growth rate. (Author's abstract) W91-11559

DRIFT OF THE CHARACIN LARVAE, BRY-CONAMERICUS DEUTERODONOIDES, DURING THE DRY SEASON FROM ANDEAN PIEDMONT STREAMS.

Maryland Univ., College Park. Dept. of Zoology. A. S. Flecker, D. C. Taphorn, J. A. Lovell, and B. P. Feifarek.

Environmental Biology of Fishes EBFID3, Vol. 31, No. 2, p 197-202, June 1991. 3 fig, 24 ref.

Descriptors: \*Fish larvae, \*Stream fisheries, \*Streamflow, \*Tropical regions, Diurnal variation, Larvae, Characids.

The downstream transport of fish larvae is well known from temperate running waters, but there exists remarkably little information for tropical exists remarkably little information for tropical streams. Drift in two Andean piedmont streams was sampled during the dry seasons of 1986-1988. Bryconamericus deuterodonoides (Characidae) larvae were found to be extremely abundant in larvae were tound to be extremely abundant in some drift collections, with peak drift densities exceeding those of temperate streams by as much as an order of magnitude. Drift of fish larvae displayed pronounced diel periodicity, with more than one-quarter of a million larvae collected during the night compared to two individuals during the day. Fish larvae were more abundant during the day. rsn inavae were more aduntant during the latter compared to early part of the dry season, even in years when streams were reduced to small isolated pools by the end of the season. These observations indicate that the dry season represents an important period of reproduction for the characid, B. deuterodonoides, and possibly other neotropical fish species. (Author's abstract)

REVIEW OF FISHERIES HABITAT IMPROVE-MENT PROJECTS IN WARMWATER

Descriptors: \*Channel improvement, \*Fisheries, \*Habitat improvement, \*Habitat restoration, \*Literature review, \*Water resources management, \*Wisconsin, Bank stabilization, Environmental pollution, Erosion control, Streams, Water temperature. Watersheds.

Over 100 publications and unpublished reports, over 30 fisheries biologists from 20 universities and natural resource management agencies, and made on-site observations of projects in Illinois and Missouri were reviewed to determine what is currentify (early 1989) known about physical habitat improvement for fisheries in warmwater streams. Previous improvement work has focused on 3 main objectives: reducing bank erosion and in-stream sediment, modifying channel morphology and alignment, and increasing in-stream cover. A wide variety of techniques appear to be useful in achieving these objectives, although few have been adequately evaluated. Based on these reviews, contacts, and observations, the following general recommendations for warm water stream habitat improvement projects in Wisconsin can be made: (1) consider the entire stream ecosystem and watershed when planning projects, and try to address fundamental underlying causes of habitat problems whenever possible; (2) before beginning a project, collect quantitative data that demonstrate a need for habitat improvement and indicate probably limiting habitat characteristics; (3) use the most cost-effective techniques to improve habitat, and rely on natural objects or simple, easily replaced structures whenever possible; (4) use all available data and expertise in determining the proper placement and installation of habitat improvement. For warm water streams in Wisconsin, the authors believe that bank revegetation coupled with the judicious use of riprap is the best approach to bank stabilization. Careful placement of boulders, trees, and rock wing dams should be effective in reducing sedimentation and increasing channel depth. Stable banks and deeper channels will improve in-stream cover. If further increases in cover are warranted, the placement of additional rocks and logs or the installation of habitaring the proper placement of additional rocks and logs or the installation of habitaring the proper placement of additional rocks and logs or the installatio

# HYDROLOGIC CHARACTERISTICS OF THE GREAT SALT LAKE, UTAH: 1847-1986.

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Supply Paper 2332, 1990. 32p, 28 fig, 3 tab, 47 ref, 1 map.

Descriptors: \*Great Salt Lake, \*Limnology, \*Utah, \*Water level, Algae, Arid lands, Ecosystems, Land use, Salinity, Species diversity.

The Great Salt Lake in Utah is a large body of water bordered on the west by barren desert and on the east by a major metropolitan area. It is the fourth largest terminal lake in the world, covering about 2,300 sq m in 1986. Since its historic low elevation of 4,191.35 ft in 1963, the lake rose to a new historic high elevation of 4,211.85 ft in 1986.

Most of the increase (12.2 ft occurred after 1982). The rise has caused \$285 million of damage to lake side industries, transportation, farming, and wild-life. Accompanying the rapid rise in lake level has been a decrease in salinity-from 28% in 1963 to about 6% in 1986. This has resulted in changes in the biota of the lake from obligate halophiles, to opportunistic forms, such as blue-green algae and most recently, a brackish water fish. (Author's abstract)

MICROCLIMATOLOGICAL INVESTIGA-TIONS IN THE TROPICAL ALPINE SCRUB OF MAUI, HAWAII: EVIDENCE FOR A DROUGHT-INDUCED ALPINE TIMBERLINE. Goettingen Univ. (Germany, F.R.). Systematisch-Gebotanisches Inst. und Neuer Botanischer Garten.

C. Leuschner, and M. Schulte.
Pacific Science PASCAP, Vol. 45, No. 2, p 152-168, April 1991. 7 fig, 3 tab, 64 ref.

Descriptors: \*Climatology, \*Drought effects, \*Hawaii, \*Maui, \*Microclimatology, \*Mountains, \*Plant-water relationships, \*Precipitation, \*Timberline, \*Tropical regions, \*Water availability, Air temperature, Cloud cover, Humidity, Soil temperature, Solar radiation, Wind velocity.

Micrometeorological measurements were made in the lower alpine zone of Mt. Haleakala on Maui, Hawaiian Islands, in March 1988 to characterize ecologically significant climatological parameters. Daily courses of photosynthetically active and total net radiation, temperatures of air, soil, and plant canopy, wind speed, air humidity, leaf wetness, and precipitation were recorded at an elevation of 2100 m in alpine scrub slightly above the timberline. A battery-powered data-logging system was used, which gave high temporal resolution. Influence of variable cloud cover on microclimate of the study site was evaluated on five selected days with highly differing weather conditions. Based on comparison with data from other high mountains of the humid tropical zone, it is concluded that the alpine timberline on Maui is caused by a complex of factors. Plant water availability is probably the dominating one; temperature seems to be of lesser importance. The extraordinary microclimatological conditions of the alpine zone of Maui are examined in the context of the atmospheric circulation system in the region of the Hawaiian archipelago. Journal of Hydrology JHTDA7, vol. 25, No. 37, 4, p 261-278, March 1991. 8 fig. 6 tab, 26 ref. Descriptors: \*Boundary layers, \*Conductance, \*Forest hydrology, \*Interception, \*Precipitation, \*Throughfall, \*Trees, Evaporation, Interception loss, Penman equation, Spruce trees, Stemflow.

The effect of tree spacing on rainfall interception loss has been investigated in stands of Sitka spruce (Picca sitchensis (Bong.) Carr) spaced at intervals of 2, 4, 6, and 8 m. The traditional volume balance method was used to measure throughfall, stemflow and interception loss between the four interception loss between the four

spacing treatments was analyzed. The variation of results obtained showed that, on average, annual interception loss as a percentage of gross rainfall was 33, 24, 15 and 9% in the 2, 4, 6, and 8m spacing treatments, respectively. An estimate of average boundary layer conductance was made by equating interception loss with evaporation rate and inverting a truncated form of the Penman equation. The boundary layer conductance per tree increased with spacing from 0.38 cu-m/s in the 2 m spacing treatment to 4.24 cu-m/s in the 8 m spacing treatment, whereas boundary layer conductance per unit area declined from 0.17 to 0.07 m/s as the density of trees decreased. The difference in interception loss between spacing treatments was attributed to the difference in the boundary layer conductance. (Author's abstract) W91-10905

Descriptors: \*Climatic data, \*Climatology, \*Plant growth, \*Precipitation, \*Trees, \*Water stress, Baldcypress trees, Cloud cover, Correlation analysis, Dendrochronology, El Nino/Southern Oscillation, Oak trees, Plant water potential.

Tree-ring chronologies of baldcypress (Taxodium distichum) and post oak (Quercus stellata) from the central U.S. are directly correlated with precipitation, and inversely with percentage possible sunshine during the growing season (March-June). Partial correlation analysis indicates that precipitation is the most important climate signal in the growth of these trees, but sunshine duration accounts for an additional 22% of the radial growth variance independently of the growth influences of precipitation or temperature. Because the internal moisture balance of trees and ultimately the width of annual tree-rings assimilate the direct and interactive effects of sunshine duration, temperature, and especially precipitation, the tree-ring fronology can explain 60% of the variance in regional sunshine duration. Consequently, the derived reconstruction retains more sunshine duration information than is reflected by the simple covariance between rainfall, cloud cover, and sunshine. A tree-ring reconstruction of sunshine duration from AD 1700 to AD 1980 suggest that short-period changes in the mean, variance, and persistence of cloud cover have occurred over the past 281 years. Analysis of the reconstruction indicates that strong El Nino events are often associated with cloudy growing season conditions over the central U.S. The full 281-year reconstruction and the 85-year instrumental sunshine data also contain prominent 5 to 10-year sunshine oscillations, which frequently help to induce trends lasting up to 20 years. The sunshine reconstruction does not, however, reveal any statistically significant 30-year-long linear trends in sunshine duration since 1700. (Author's abstract)

MICROWAVE TRANSMISSION, A NEW TOOL IN FOREST HYDROLOGICAL RESEARCH. Amsterdam Univ. (Netherlands). Lab. for Physical Geography and Soil Science. W. Bouten, P. J. F. Swart, and E. De Water. Journal of Hydrology JHYDA7, Vol. 124, No. 1/ 2, p 119-130, April 1991. 6 fig, 28 ref.

Descriptors: \*Evaporation, \*Forest hydrology, \*Instrumentation, \*Interception, \*Microwaves, \*Plant-water relationships, \*Throughfall, Analytical models, Automation, Canopy, Fir trees, Forest watersheds, Hydrologic models, Precipitation, The Netherlands, Water storage.

After several decades of interception studies, there are still considerable gaps in the understanding of wet-canopy evaporation. Model development is wet-canopy evaporation. Model development is being obstructed by the lack of techniques for the measurement of state and rate variables which have to be quantified for model validation. The applicability of microwave attenuation measure-ments for the determination of canopy wetness was examined. The attenuation caused by a single spruce fir in the laboratory and the vertical attenu-ation profiles of a Douglas fir stand were measured under dry and wet conditions. The results indicate increase of the attenuation upon wetting and a under dry and wet conditions. The results indicate increase of the attenuation upon wetting and a decrease owing to drip and evaporation after rainfall ceased. From the results, conclusions have been drawn on the design of instrumentation for an optimized measuring system which is suitable for unattended automated scanning of canopy water storage. This system has been calibrated, using sesticible in several account. storage. In system has been childraced, using vertically integrated microwave attenuation profiles and canopy water budgets from precipitation and throughfall measurements. This system will be used for a forest hydrological study in the framework of the Dutch ACIFORN project, a research project on the effect of atmospheric deposition on Douglas fir vitality. INFLUENCE OF LEAF LEACHATE-EN-RICHED WATER OF NEEM (AZADIRACHTA INDICA A. JUSS) AND SHIRISH (ALBIZZIA LEBBEK BENTH.) ON THE GROWTH OF EICHHORNIA CRASSIPES (MART.) SOLMS. Burdwan Univ. (India). Dept. of Botany. Q. Taheruzzaman, and D. P. Kushari. Aquatic Botany AQBODS, Vol. 40, No. 1, p 1-9, April 1991. 1 fig. 1 tab, 46 ref.

Descriptors: \*Ephemeral streams, \*Neem, \*Plant growth, \*Shirish, \*Water hyacinth, Biocontrol, Biomass, Chlorophyll, Growth, India, Leaching, Leaves, Light effects, Nitrates, Nitrogen, Nutrients, Phosphates, Phosphorus, Salts, Seasonal variation

An experiment was conducted to determine the seasonal effects of water enriched by neem (Azadirachta indica) and shirish (Albizzia lebbek) on the growth of water hyacinth (Eichhornia crassipes) collected from ditches in Burdwan (India). Stocks were cultivated outdoors in concrete tanks containing pond water and sediment with or with-out fresh leaves of the two terrestrial species. Total out fresh leaves of the two terrestrial species. Total soluble salts were greatest in neem-treated water, followed by shirish, in summer. Maximum nitrate mitrogen was recorded in shirish-treated water, followed by neem, in summer. Maximum phosphate phosphorus was noted in neem water, followed by shirish. The rate of change of Eichhornia biomass varied seasonally, but was always far higher in leaf-treated water. The growth of Eichhornia was not sharply affected by shade conditions, although maximum crowth was noted in neem water (75 41). maximum growth was noted in neem water (75.41 g fresh weight) in the open area. Chlorophyll content was always higher in partial shade. The

higher growth rate of Eichhornia in water en-riched with different leaves in different shade conditions may be related to more leaching of nutri-ents from the leaves. The higher growth in neem-enriched water might also be related to the release of some chemical substances that could inhibit the growth of pests and diseases that would otherwise suppress plant growth. INFLUENCE OF FLOODED SOIL ON CHEMI-CAL COMPOSITION OF ANNUAL RYEGRASS AND DIGESTIBILITY BY MEADOW VOLES. Massey Univ., Palmerston North (New Zealand). T. H. Terrill, V. G. Allen, J. P. Fontenot, J. A. Cranford, and J. G. Foster. Virginia Journal of Science VJSCAI, Vol. 42, No.

Descriptors: \*Chemical composition, \*Flooding, \*Forages, \*Grazing, \*Nutrients, \*Rodents, Absorption, Acidity, Aluminum, Amino acids, Cellulose, Copper, Grasses, Greenhouses, Iron, Magnesium, Minerals, Organic acids, Phosphorus, Soil moisture, Soil types, Zinc.

1, p 101-112, Spring 1991. 5 tab, 31 ref.

Flooding affects mineral composition of pasture grasses, but little is known concerning effects on fiber, organic acid and amino acid composition, fiber, organic acid and amino acid composition, dry matter digestibility, and mineral absorption by animals. 'Gulf' annual ryegrass (Lolium multi-florum) was grown on a Bucks loam (Typic Hapludit, fine-loamy, mixed, mesic) in a greenhouse to investigate the influence of flooding and 80% field investigate the influence of Hooting and sorts mean capacity (FC) soil moisture on plant growth and chemical composition. Flooding increased soil pH, tended to increase soil exchangeable Al (modified aluminon method), and increased Al, Fe, Cu, neuaumnon metrody, and increased Al, re, Cu, neu-tral detergent fiber (NDF), acid detergent fiber (ADF), hemicellulose, alanine, valine, and gluta-mate concentrations in ryegrass herbage. Magnesi-um, K, Zn, malate, fumarate, and succinate conum, K, Zn, malate, fumarate, and succinate con-centrations were decreased by flooding. Meadow voles (Microtus pennsylvanicus) were fed the for-ages grown at two moisture levels over an 8-day period to evaluate mineral availability and forage digestibility. Apparent absorption of Mg and K was decreased in animals fed forage grown on flooded soil, but absorption of Al, Fe, and P tended to increase. Results suggest that forages grown under flooded conditions have altered amino acid, organic acid. mineral. and fiber conamino acid, organic acid, mineral, and fiber con-centrations, which could result in lowered per-formance of animals grazing these forages. #### 2J. Erosion and Sedimentation

ADVANCES IN WIND AND WATER EROSION PREDICTION.

Minnesota Univ., St. Paul. Dept. of Agricultural Engineering.

Journal of Soil and Water Conservation JSWCA3, Vol. 46, No. 1, p 27-29, January/February 1991. 2 fig, 22 ref.

Descriptors: \*Computer models, \*Erosion, \*Erosion rates, \*Model studies, \*Universal soil loss equation, \*Wind erosion, Forecasting, Soil erosion, Water Erosion Prediction Project, Wind Erosion

Erosion prediction is a powerful tool used by soil conservationists for almost five decades. Although several erosion equations have been developed, the most popular one by far is the universal soil loss equation (USLE) developed by W. H. Wischmeier for sheet and rill erosion. A similar equation for predicting erosion by wind is the wind erosion equation (WEQ). These equations are used almost exclusively by the Soil Conservation Service and other user agencies. The potential is great for improvements in erosion prediction technology.

The USDA Water Erosion Prediction Project improvements in evosion prediction terminology. The USDA Water Erosion Prediction Project (WEPP) started in 1985 has developed the land-scape profile version of the model and its companion computer program to fulfill the first phase of the project to develop new generation, processbased technology for predicting erosion by water. Whereas the USLE considers only the eroding portion of landscape profile, WEPP technology considers erosional and depositional portions of landscape profiles, ephermeral gullies within the fields, complex flow patterns within fields, and the variation of erosion over complex fields that vary variation of erosion over complex fields that vary in topography, soil, cropping, and management. Even though WEPP is very much process-based, it does not answer all questions. Gaps and areas needing dramatic improvements include: better definition of flow patterns over the soil surface; better model structure to represent these flow pat-terns; improved understanding of erosion processterns; improved understanding of eroson process-es; and improved understanding of how fundamen-tal soil properties affect erodibility and infiltration, especially as these processes are modified by cli-mate, tillage, cropping, and management. RUSLE: REVISED UNIVERSAL SOIL LOSS

Agricultural Research Service, Tucson, AZ. K. G. Renard, G. R. Foster, G. A. Weesies, and J.

Journal of Soil and Water Conservation JSWCA3, Vol. 46, No. 1, p 30-33, January/February 1991. 1 tab, 4 ref.

Descriptors: \*Computer models, \*Erosion, \*Revised Universal Soil Loss Equation, \*Soil erosion, \*Universal soil loss equation, Agricultural practices, Erosion rates, Forecasting, Rill erosion, Slope degradation, Soil conservation.

The Universal Soil Loss Equation (USLE) is a powerful tool that has been used by soil conserva-tionists for almost three decades for on-farm planning of soil conservation practices, inventorying and assessing the regional and national impacts of erosion, and developing and implementing public policy related to soil conservation. A Revised Universal Soil Loss Equation (RUSLE) has been deversal Soil Loss Equation (RUSLE) has been developed over the past three years. Some of the improvements include: a greatly expanded erosivity map for the western U.S.; minor changes in Ractors (input that drives the sheet and rill erosion process) in eastern U.S.; expanded information on soil erodibility; slope length factor that varies with soil susceptibility to rill erosion; a nearly linear slope steepness relationship that reduces computed soil loss values for very steep slopes; a subfactor method for computing values for the cover-management factor; and improved factor values for the agement factor; and improved factor values for the effects of contouring, terracing, striperopping, and management practices for rangeland. RUSLE will be implemented using a computer program that, along with documentation, will be available soon. Differences in soil loss estimates between the RUSLE and USLE vary from more to less erosion for individual locations depending on specific factor value changes. (Mertz-PTT)

WEPP: A NEW GENERATION OF EROSION PREDICTION TECHNOLOGY.

National Soil Erosion Lab., West Lafayette, IN. J. M. Laflen, L. J. Lane, and G. R. Foster.

Journal of Soil and Water Conservation JSWCA3, Vol. 46, No. 1, p 34-38, January/February 1991. 3

Descriptors: \*Computer models, \*Computer programs, \*Erosion, \*Soil erosion, \*Water Erosion Prediction Project, Computers, Erosion rates, Soil conservation, Universal soil loss equation.

The Water Erosion Prediction Project (WEPP) represents a departure from factor-based erosion prediction technology to a new process-based technology. As new studies are conducted and more computer power becomes available, WEPP will provide a basis for inserting improved process descriptions and parameter values that will provide improved technology for prediction of soil erosion. The WEPP effort is a multistep process that included: development of a user-requirements document; evaluation and targeting of critical research to be accomplished before the technology could be

# Erosion and Sedimentation—Group 2J

used; identification of a core team of scientists to produce the various components; development of an operational computer program; development and completion of an implementation plan that and completion of an implementation plan that included validation and testing of the portion of WEPP that computes soil erosion and evaluation and testing of the user-friendly components of the operational computer program. As with the Universal Soil Loss Equation, WEPP is intended to be a living technology that provides the framework for a technology for a long period of time. The power of WEPP holds great promise for addressing important natural resource issues in ways that they need to be addressed but in the past could be they need to be addressed but in the past could not be because of limitations in the predictive technology. WEPP: SOIL ERODIBILITY EXPERIMENTS FOR RANGELAND AND CROPLAND SOILS. National Soil Erosion Lab., West Lafayette, IN. J. M. Laflen, W. J. Elliot, J. R. Simanton, C. S. Holzhey, and K. D. Kohl. Journal of Soil and Water Conservation JSWCA3, Vol. 46, No. 1, p 39-44, January/February 1991. 10 fig, 1 tab, 20 ref.

Descriptors: \*Computer models, \*Erosion, \*Model studies, \*Rill erosion, \*Soil erosion, \*Water Erosion Prediction Project, Computer programs, Cropland, Range management, Soil transport.

The Water Erosion Prediction Project (WEPP) ombines knowledge of soil erosion processes with other important processes in a simulation model to predict soil erosion by water. WEPP models soil erosion as a process of rill and interill detachment and transport. A study on rangeland and cropland soils has been conducted over much of the U.S. to produce the data base needed to estimate soil erodibility for application of WEPP to the nation's soils. Analyses indicate that the soil erodibility soils. Analyses indicate that the soil erodibility values bear little quantitative resemblance to Universal Soil Loss Equation (USLE) soil erodibility values, but variables important in determining USLE soil erodibility values, such as particle size distribution and organic matter content, may also be important in determining WEPP soil erodibility values. Extremely high erosion rates may occur in rills, particularly if flow rates are high and slopes are fairly steep. Some of these rates are so high that they should be cause for immediate concern. These rates are realistic on freshly tilled soils, and were observed in the WEPP field studies. They were observed in the WEPP field studies. They also were supported by field observations of soil removal in rills and ephermeral gullies. In addition, as surface water quality becomes a greater concern, the use of the WEPP erosion technology to evaluate the chemicals transported in surface runoff will become more important. INVESTIGATION OF LOCAL SCOUR IN CO-HESIONLESS SEDIMENTS USING A TUNNEL-MODEL.

Waterloopkundig Lab. te Delft (Netherlands).

M. Buchko, P. Kolkman, and K. Pilarczyk. Available from the National Technical Information Service, Springfield, VA. 22161, as PB90-134065. Price codes: A03 in paper copy, A01 in microfiche. Publication No. 393, December 1988. 11p, 7 fig, 2 tab, 5 ref.

Descriptors: \*Erosion, \*Hydraulic models, \*Model studies, \*Scour, \*Tunnels, Flow pattern, Flow velocity, Hydraulic structures, Mathematical studies,

Erosion of soil near hydraulic structures is usually studied in hydraulic models using Froude similitude. With free surface flow, exaggeration of the velocity is used only when the Froude number is small (the water level nearly horizontal). Erodability is not well reproduced with finer grain sizes, and empirical relationships have to be used for extrapolation to prototype. Parameters of interest in the design of hydraulic structures and bottom protection are: rate of scouring, step discontinuities at the upstream end of the scour hole, scour hole slopes, and the equilibrium scour depth. Two-dimensional sand erosion tests in a closed water tunnel (velocities up to 2 m/s) produced a scour hole downstream in a sill or flat bottom protection. The slope of the scour hole was independent of hole downstream in a sill or flat bottom protection. The slope of the scour hole was independent of flow velocity and partially dependent on scale; and wholly dependent on grain size, grain-size gradution, and sill geometry. Tractive forces on single grains and bed liquefaction are the mechanisms of scour. (Lantz-PTT)

ORGANIC CARBON ACCUMULATION IN BAFFIN BAY AND PALEOENVIRONMENT IN HIGH NORTHERN LATITUDES DURING THE

PAST 20 M. Y.
Giessen Univ. (Germany, F.R.). Inst. fuer Geowissenschaften und Lithospharenforschung.

Geology GLGYBA, Vol. 19, No. 4, p 356-359, April 1991. 3 fig, 29 ref. Deutsche Forschungsge-meinschaft Grant No. STE 412/1.

Descriptors: \*Climatic changes, \*Cores, \*Greenland, \*Organic carbon, \*Paleoclimatology, \*Sediment transport, \*Sedimentation rates, Accumulation, Glacial drift, Glaciation, Pollen, Snowmelt, Spores, Tundra, Vegetation.

The results of the investigation of organic carbon deposition in Baffin Bay, Greenland, provide important information about paleoenvironmental evolution in high northern latitudes during Cenozoic time. During Miocene to Quaternary time, organic carbon enrichment of up to 3% in sediments sam-pled at Ocean Drilling Program Site 645 was conpled at Ocean Drilling Program Site 645 was controlled mainly by an increased supply of terrige-nous organic matter. Two distinct maxima were identified: (1) a middle Miocene maximum, possibly reflecting a dense vegetation cover and fluvial sediment supply from adjacent islands, which decreased during late Miocene and early Pilocene time because of expansion of tundra vegetation due to global climatic deterioration; and (2) a late Pilocene-Pleistocene maximum probably caused by glacial erosion and meltwater outwash. Significant amounts of marine organic carbon were deposited in Baffin Bay during middle Miocene time, suggesting higher surface water productivity triggered by the inflow of cold and nutrient-rich Arctic water masses. The decrease in average surface water productivity to values similar to those of modern Baffin Bay occurred during the late Miomater productivity to values similar to those of modern Baffin Bay occurred during the late Mio-cene and were probably caused by development of a seasonal sea-ice cover, reaching maximum expan-sion during the past 3.4 m.y. (Author's abstract) W91-10791

FAST ALGORITHM FOR AUTOMATICALLY COMPUTING STRAHLER STREAM ORDER, Geological Survey, Reston, VA. Water Resources

Water Resources Bulletin WARBAQ, Vol. 26, No. 6, p 977-981, December 1990. 2 fig, 5 ref.

Descriptors: \*Algorithms, \*Computer programs, \*Geographic information systems, \*Geomorpho-

logy, \*Stream classification, \*Stream order, \*Terrain analysis, Computation time, Digital map data, Headwaters, Raritan River, Strahler stream order,

In the Strahler system for ordering a stream network, all headwater streams (i. e., streams shown on the map, but into which no other streams flow) are assigned an order of 1. The order increases as one proceeds downstream. Since numbering begins in the headwaters, the Strahler stream order is dependent on the resolution of the stream network depicted on the source map. In a Geographic Information System (GIS), a stream network can be represented as a series of connected arcs. Each arc is an ordered set of x,y coordinates that identiarc is an ordered set of x,y coordinates that identifies the location or tracing of a stream segment. Stream locations may be derived from a digital elevation model (DEM) using an algorithm. An efficient algorithm has been developed to determine Strahler stream order for segments of stream networks represented in a GIS for the Raritan networks represented in a GIS for the Raritan River. Where digital elevation data of adequate resolution are available, this technique offers the prospect of deriving the stream network in much greater detail and consistency than is generally shown on existing maps. The execution time for the algorithm was shown to vary nearly linearly with the number of stream segments in the network making it practical to use for analysis of large stream networks. (Korn-PTT) large stream networks. (Korn-PTT) W91-10818

SEASONAL INFLUENCES ON THE SEDI-MENT TRANSPORT CHARACTERISTICS OF THE SACRAMENTO RIVER, CALIFORNIA.

HE SACRAMENTO RIVER, CALIFORNIA. Bradford Univ. (England). Dept. of Civil Engineering and Structural Engineering. P. Goodwin, and R. A. Denton. Proceedings of the Institution of Civil Engineers PCIEAT, Vol. 91, No. Pt 2, p 163-172, March 1991. 4 fig, 13 ref.

Descriptors: \*California, \*Mathematical models, \*Model studies, \*Sacramento River, \*Seasonal variation, \*Sediment transport, \*Suspended sediments, Energy gradient, Hydrodynamics, Sediment analysis, Streamflow.

Field measurements of suspended sediment transport and streamflow collected by the Unites States Geological Survey on the Sacramento River from 1953 to 1976 were studied. Analysis of data show that the quantity of sediment transported by a given discharge can vary by nearly two orders of magnitude and that the first major flows following magnitude and that the first major flows following the dry season tend to transport more sediment than comparable discharges at other times in the year. Simple statistical tests were used to show that the peaks in suspended sediment load tend to lead peaks in streamflow at this site. The ramifications of these observations in assigning suitable boundary conditions in mathematical models were analyzed. These simple observations at a specific site show that substantial inaccuracies can be introduced at the boundaries of mathematical models. show that substantial inaccuracies can be introduced at the boundaries of mathematical models predicting sediment transport, particularly for long-term simulations. These errors will lead to inaccurate sediment predictions, and may initiate artificial bed transients and affect the hydrodynamic field. Detailed information with respect to energy slope, resistance characteristics, bed armoring, sediment size and availability should also be used, wherever possible, to establish a realistic boundary condition. # Group 2J-Erosion and Sedimentation

kalinity, Calcium, Chemical composition, Chlorides, Core sampling, Magnesium, Organic matter, Salinity, Sulfates, Tyrrhenian Sea.

Seven gravity core samples were collected from the Tyrrhenian Sea in order to study the type of interstitial water as well as the diagenetic processes governing sedimentation in the western Mediterra-nean during the Holocene. No drastic changes in nean during the Folocene. No drastic changes in the chemical composition of interstitial water oc-curred in the carbonate sediments of the Tyrrhen-ian Sea which preserved their original type, i.e., oceanic type (MgSO4). Aerobic conditions prevail-ing during the Holocene may explain this phe-nomenon. Normal values of salinity (averaging 38) were found, except in the southern part of the sea where a value of 43.88 was recorded. The chemical composition of interstitial water of this region has been influenced, to some extent, by volcanic has been influenced, to some extent, by volcanic activity and by infiltration of brines from the underlying Messinian evaporites. Alkalinity was low for most of the investigated core samples. This can be attributed to the weak effect of biogenic processes such as oxidation of organic matter and sulfate reduction. The slight tendency for decreasing alkalinity, Ca, Mg, Ca/Mg, Ca/Cl and Mg/Cl of interstitial water with depth in sediments for some core samples may reflect limited development of ion-exchange and adsorption processes between sediments and interstitial water. Major oil and gas discoveries in the shallow waters near Richards Island, N.W.T., Canada, have crenear Kichards Island, N. W. I., Canada, have cra-ated an urgent need for regional and site-specific knowledge of geological, geotechnical, and geo-thermal conditions of the coastal zone of the south-ern part of the Beaufort Sea. These areas can be expected to show considerable variability in litholexpected to snow considerable variability in intology, strengths, and geothermal setting both in a temporal and a spatial sense. Drilling and laboratory studies carried out along onshore-offshore transects at a stable coastal site and an actively eroding coastal site have identified six major stratigraphic units of Holocene and pre-Holocene (Wisconsinan age). The main factors controlling the geotechnical properties of these sediments and their distribution are the occurrence of shallow permafrost beneath areas seasonally covered by landfast sea ice, rapid degradation of permafrost in areas farther offshore, ice content of thawing pre-Holocene sediments, and variability in coastal processes. The design of shallow and deep foundations in this environment must consider all aspects of the thermal and geological regimes at any site located in the nearshore zone. Site surveys should include an overview of zone. Site surveys should include an overview of regional coastal geology, including coastal processes and permafrost regime. Potential problems that may influence foundation design include the widespread occurrence of shallow permafrost; high rates of coastal erosion or deposition, deformation, or disruption of local stratigraphy owing to glacio-tectonics; thaw settlement owing to degradation of permafrost, liquefaction, and high pore-water salin-ities. SEPTEMBER 5, 1987, LANDSLIDE ON THE LA GRANDE RIVER, JAMES BAY, QUEBEC, CANADA.

Sherbrooke Univ. (Quebec). G. Lefebvre, P. Rosenberg, J. Paquette, and J. G.

Canadian Geotechnical Journal CGJOAH, Vol. 28, No. 2, p 263-275, April 1991. 12 fig, 2 tab, 6 ref. Descriptors: \*Bank erosion, \*Canada, \*Erosion, \*Landslides, \*Slope stability, \*Stream banks, Avalanches, Groundwater movement, Quebec, Shear stress, Slopes, Soil stability, Subsurface drainage.

The September 5, 1987, a landslide at kilometer 82.5 on La Grande River, James Bay, Quebec, Canada, affected a slope about 60 m high inclined at about 35 degrees. The site had been identified as presenting high risks of a major landslide and had been under observation for several years. The conditions existing before the landslide are relatively well documented from a deep boring put down in 1975 at the slide location and from prior observa-tions and photographs of the river bank erosion. The overburden deposit, sand at the ground sur-The overotiruen deposit, sand at the ground sufface changing to a silly clay at depth, was normally consolidated but affected by a strong underdrainage. Stability analyses confirm the strong underdrainage deduced from the 1975 piezometric reading. The silde retrogressed 290 m from the river on a surface inclined at 6 degrees. The retrogression devalored in the clawse sill have the gression developed in the clayey silt layer that forms a weaker transition between the granular material above and the silty clay below. The location of the retrogression surface appears related to the undrained shear strength profile; the actual location of the retrogression surface is above a jump of about 50 kPa in the undrained shear strength profile. Of all the factors behind this localized increase in shear strength, the most important appears to be a rapid increase in effective stress owing to an important underdrainage. Parametric effective stress analyses of the first slide indicate that to stand with the preside geometry, the slope needed an underdrainage equivalent to a ratio of about 0.1, which is in good agreement with the groundwater regime inferred from the 1975 data and observed at other sites in the area. This site confirms the important role of the groundwater regime in the slope-stability conditions of high riverbanks. (Fish-PTT) W91-10946

Measurement of sedimentation variables in lakes has made it possible to identify the processes gov-erning sediment movement and accumulations. Sediment cores from 21 locations in Lake Michigan were evaluated to identify sedimentation pat-terns including accumulation rates, surface layer mixing, focusing, and processes responsible for dis-continuous 210-Pb profiles. These patterns were identified based on two different sediment dating identified based on two different sediment dating models. Accumulation ratter vary consistently with basin topography in the north and central areas of the lake, while rates in the southern basin vary widely between sites. Mixing is apparent in all north basin sites but is seldom observed in the south basin and not in the central lake. Storm surges have influenced sediment accumulation, particularly in the south basin where sites are identified that have lost and gained sediment resulting from a storm. In particular, evidence was found of the 1888, 1905, and, most recently, the 1975 storms. Markers for these storms were not 1975 storms. Markers for these storms were not previously reported for Lake Michigan. Storm-related slumps and sand layer discontinuities were also identified. An extended period of dry and hot weather during 1913-1952 may have caused periodic lower sedimentation rates in the north basin, but not in the south where sediment redistribution but storms has obliterated records. Sediment focus. by storms has obliterated records. Sediment focusing is a minor process in the north basin, while in the south, the areas of highest sediment accumula-tion rates are also sites of highest measured focus-

ing, indicating that redistribution is a major variable in south basin sedimentation processes. (Author's abstract)

ACOUSTIC PARAMETRIC ARRAY FOR MEASURING THE THICKNESS AND STRATIGRAPHY OF CONTAMINATED SEDI-

Acoustic mapping and monitoring of thin contami-nated sediments in inland waters requires an optimized acoustic source. An experiment conducted in Hamilton Harbour, Lake Ontario, demonstrated that high resolution recording of sediment layering is possible when a parametric acoustic source is used. Good correlation was obtained with the straigraphy of cores from the test site, and parametric records revealed a 4-cm ooze layer at the surface that could not be resolved using a conventional acoustic source. The encouraging performance of the parametric source for measuring thickness of sediments, which is typically not amenable to secuments, which is typically not amenable to acoustic measurement, suggests that an acoustic parametric array might be a useful tool for moni-toring sedimentation processes or for high-resolu-tion surveys of modern sediment thickness and volume. The fundamental phenomenon occurring during transport of clastic particles by fluid flow is the displacement of individual grains. Distributions of distance of bedload particle movement were examined in two gravel-bed streams (Negev and Juden Deserts, Israel) using 450 magnetically tagged cobbles and pebbles at one site and 245 such particles bles and pebbles at one site and 245 such particles at the other. The compound Poisson model of Einstein-Hubbell-Sayre and a simple gamma function model were compared with observed distributions of moved particles and of all particles. Both models fit the data reasonably well for small mean displacements, but notable misfits occurred in an event with large mean displacement. When mean particle travel distance approaches the scale of bar event with large mean displacement. When mean particle travel distance approaches the scale of bar spacing, trapping in the bars interrupts particle progress and the dispersion process. The data remain very noisy, so definitive discrimination of suitable models will require trials with more than 1000 particles. (Author's abstract) W91-11231

Using the Strahler-Schumm hierarchical classifica-tion on topographic maps with a 1:50,000 scale, a morphometric study was made of the whole hy-drographic network of the Basque Country (north-ern Spain). By applying Horton's bifurcation radius (law of number of river beds), the law of allome-tric growth, the longitudinal profile and the hypso-metric curve, it was determined that geomorpholo-gical heterogeneity due to orographic, climatic, lithological and tectonic factors is 95.77% in the river basins of Vizcaya, 73.96% in those of Gui-puzcoa, and 14.03% in those of Alava, with re-spect to isometrics. This is due to two crosion strategies in the river networks: vertical in Guipuz-Using the Strahler-Schumm hierarchical classificaspect to isometrics. This is due to two erosion strategies in the river networks: vertical in Guipuzcoa and horizontal in Alava. In Vizcaya both types are present. These strategies are related to the dynamics of the rivers' ecosystems. Where horizontal erosion predominates the river shows more conspicuous autotrophy in its middle reaches and generally has a higher primary production. Where vertical erosion prevails, heterotrophy predominates with allochthonous energy prevailing from the banks. These rivers generally have greater forest cover on the banks, and heterotrophy dominates from first-order water courses to fourth-order ones. These data are useful in calculating the nates from Inst-order water courses to fourth-order ones. These data are useful in calculating the potential risk of floods, establishing a comparison with the real risk and modeling ecological flow rates. (Geiger-PTT) W91-11265

A theory is presented for the decay of sedimentary organic matter made of a spectrum (a continuous distribution of an infinite number) of reactive types which can be characterized by a variable function of the decay constant, k. A fundamental property of the continuum theory is that it can generate an apparent order of reaction for the decay of the total mixture greater than one. The apparent order is related to the predominance of the more refractory components of the continuum relative to the more reactive. The continuum model, based on the Gamma distribution, requires half as many parameters as the traditional multi-exponential model. The continuum model was applied to nine organic matter profiles taken in non-mixed sediments or below the mixed layer in bioturbated sediments or below the mixed layer layer and layer A theory is presented for the decay of sedimentary dramatically more involved than those of the G-model. For those who insist on an analytical solu-tion, the continuum model would appear to be at a practical, but not conceptual, disadvantage in this case unless the mixed zone can be assumed to extend to infinity. While the continuum theory may initially suggest a complicated treatment for the energetics of the decay process, it was shown that for the temperature range normal to sedimen-tary environments, the Arrhenius plot can still be used to derive an effective activation energy for used to derive an effective activation energy for the total organic mass. ### Chemical Processes—Group 2K

There is geochemical evidence that magnetite is formed during the reduction of Fe(III) coupled to organic matter oxidation in anaerobic environments. Furthermore, it is known that the oxidation of organic matter coupled to Fe(III) reduction is primarily catalyzed by the direct enzymatic activity of dissimilatory Fe(III)-reducing bacteria. Studies with microbial cultures have supported the conclusion that magnetite is an end product of microbial Fe(III) reduction. The production of magnetite appears to be a nonenzymatic reaction in which the Fe(III) produced during Fe(III) reduction reacts abottically with Fe(III). The extent of magnetite production is controlled by other nonenzymatic reactions, such as siderite formation, that compete for Fe(II). Dissimilatory microbial Fe(III)-reduction appears to have generated favorable conditions for magnetite formation in such diverse sedimentary environments as the ancient iron formations, hydrocarbon seeps, rice paddy formed during the reduction of Fe(III) coupled to diverse sedimentary environments as the authention formations, hydrocarbon seeps, rice paddy soils, and freshwater and marine sediments. However, how much of the remnant magnetization of various sediments is the result of authigenic production of magnetite during dissimilatory Fe(III) reduction and how much can be attributed to soil-derived magnetite, or the magnetite of magnetotactic bacteria is an important unresolved question. A highly sensitive technique has been developed for the rapid determination of Fe(II) and total dissolved from in seawater. The technique employs flow injection analysis and chemiluminescence denow injection analysis and chemiuminescence de-tection (FIA-CL). The light is emitted by the reaction of brilliant sulfoflavin with hydrogen per-oxide and Fe(II) in a neutral medium. A cation-exchange column is used to preconcentrate the exchange column is used to preconcentrate the irron from seawater. The detection limit was 0.45 nmol/L when 4.4 mL of sample was passed through the column. Lower detection limits are attainable with larger sample volumes. The relative standard deviation is 2-5% for concentrations greater than 2.5 nmol/L. A typical analysis can be performed in 5 min. The technique was determined to be accurate based on the analysis of the North

The thermal springs of Hot Springs National Park in Arkansas are radioactive and have been a natu-ral resource of international renown which have rai resource of international renown which have attracted many tourists for many years. A study was made to learn the types and measure the levels of radioactive emissions found within the park boundaries and to determine if the emissions pose a obundants and to determine in the emissions pose a significant health hazard to the public or to park workers. The radioactivity of the hot spring waters is due mostly to dissolved radon and radon daugh-ters with a small contribution from radium. Radon concentrations were measured using passive alpha track monitors and, in some cases, activated chartrack monitors and, in some cases, activated char-coal canisters. A pressurized ion chamber and en-vironmental thermoluminescent dosimeters were used to make differential and integral exposure measurements of radon daughters. The largest ex-posure rates were observed from springs located at higher elevations. Rates decreased considerably at lower levels. This is probably due to the migration lower levels. This is probably due to the migration of radon gas back up the gravity collection system to higher elevations. A highly localized area of relatively intense gamma radiation was found at an abandoned spring site on the upper slopes. Radon levels in dwellings and other park buildings are below any current action level. Bathhouse basements have some potential for becoming hazardous but this can probably be remedied with ventilation and sealing of cracks. The highest external exposures exist over and immediately adjacent to therand sealing of cracks. The highest external expo-sures exist over and immediately adjacent to ther-mal spring openings. Essentially all spa areas were well within acceptable radiation exposure limits. Radon and daughters comprise essentially all of the radioactivity present in the park. Dried-up springs no longer emit gamma rays. The presence of water is evidently necessary for gamma emis-sions to exist. (Medina-PTT) W91-10846

Sediment composition and interstitial water concentrations of soluble reactive phosphorus (SRP), dissolved iron, ammonia nitrogen and dissolved organic carbon and pH were monitored at 5 sampling stations in the shallow Lake Loosdrecht (Netherlands). The differences in concentrations between the sediments were much larger than the differences in overall sediment composition. The concentrations of SRP and ammonia were strongly correlated, and the ratio between them was close to that predicted from a mineralization model. Possibly, the high concentrations of refractory organic material in the sediments affect the availabil-ity of iron. The pore water was calculated to be frequently supersaturated with respect to vivianite. However, this did not seem to affect the phosphate concentrations in the pore water. (Author's ab-

Heavy metals, Narragansett Bay, Phytoplankton. For most phytoplankton, a close correlation has been found between trace metal speciation and biological response (including metal uptake, bioconcentration, bioavailability, and toxicity). Recent studies on the complexation of zinc in estuarine, neritic, and upper-ocean environments have pointed to the importance of organic substances-both molecular and colloidal-in the speciation of zinc. Anodic stripping voltammetry (ASV) at the rotating disk electrode was used to probe the zinc-organic ligands interactions in Narragansett Bay Water samples and in samples collected in the Slope Water region off the U.S. mid-Atlantic Bight. In Narragansett Bay Water, two distinct groups of complexing ligands were detected, which have conditional stability constants (log K) of 7.7 and 7.0 and represent solution and surface complexation respectively. In samples collected near the western edge of the Gulf Stream two classes of dissolved organic ligands could be distinguished, with average stability constants (log K1, log K2) of 9.3 and 7.6. Because of the complexity of the systems studied, the complexation properties of these ligands had to be measured over a range of of the systems studied, the complexation properties of these ligands had to be measured over a range of of these figands had to be measured over a range of pH values and/or a range of electrode rotation rates, to obtain correct and precise estimates of their stability constants. This type of approach gave a complex but coherent interpretation of all ASV data (i.e. variation of the ASV signal with

zinc concentration, pH and electrode rotation rate), and is to be particularly recommended to workers confronted with new or complex marine systems. (See also W91-10926) (Agostine-PTT) W91-10924

MEASUREMENT OF THE DIFFERENT FORMS OF ZINC IN NARRAGANSETT BAY WATER BASED ON THE RATE OF UPTAKE BY A CHELATING RESIN.

Naturally occurring organic ligands in seawater may keep the free metal ion concentration nearly constant, in the range required for phytoplankton constant, in the range required for phytoplankton growth. A chelating ion-exchange procedure based on total exchange of the free metal was used to establish the rate laws describing the release of zinc from the particulate and dissolved organic forms naturally occurring in Narragansett Bay water. Batch treatment with Chelex-100 ion exchange resin was used to quantify the physico-chemical forms of zinc in Narragansett Bay water samples collected on seven dates between November 1982 and January 1986. Labile complexes of samples collected on seven dates between November 1982 and January 1986. Labile complexes of zinc in solution were rapidly taken up (100% uptake after 0.5 h); another two kinetically distinguishable components of the zinc pool were identified as 'moderately labile' organic and 'slowly labile' particulate forms, respectively. The first component followed pseudo-first-order kinetics of dissociation, whereas the particulate component gave a removal plot that could best be described as zero order. Although the distribution of zinc between sampling dates the rate constant charactertween sampling dates, the rate constant character-izing the release of zinc from each component showed little variation with season and tidal phase. One sample differed from the above analysis in that One sample different from the above analysis in that the removal of particulate zinc was found to conform to a surface binding site kinetic analysis, from which the first-order desorption rate constant was obtained. Groundwater from wells in the Cambrian-Ordovician sandstone aquifer of eastern Wisconsin often contains elevated concentrations of dissolved solids, chloride, and sulfate, and locally approaches or exceeds the current drinking water standard for combined radium activity. Samples were collected combined radium activity. Samples were collected from wells located along an approximate flow line in order to gain an improved understanding of the chemical evolution of groundwater in this system. It was found that the concentrations of chloride, sulfate, and sodium increase where the aquifer is

#### Chemical Processes—Group 2K

confined by the Maquoketa Shale, and the highest combined radium activity is also found in this area. Charge balance calculations and geochemical mod-eling indicate that dissolution of trace evaporite minerals and cation exchange are important mechanisms controlling major ion distribution. Isotopic equilibrium calculations and analysis of well cuttings from one well with alpha-sensitive film indicate that the dissolved radionuclide activities are consistent with a uranium source occurring in shaly intervals of the sandstone aquifer at maxi-mum local concentrations of 5 ppm. INFLUENCE OF GREEN PLANTS ON THE WORLD CARBON BUDGET.

Institute of Tropical Forestry, Rio Piedras, PR. A. E. Lugo.

A. E. Lugo.

In: Environmental Problems and Solutions: Greenhouse Effect, Acid Rain, Pollution. Hemisphere Publishing Corporation, New York. 1990. p 79-86. 2 fig. 1 tab, 23 ref. US DOE Contract No. EV-78-S-036047.

Descriptors: \*Atmospheric chemistry, \*Carbon cycle, \*Mathematical models, \*Model studies, cycle, \*Mathematical models, \*Model studies, \*Vegetation effects, Anthropogenic effects, Carbon uptake, Ecosystems, Marine environment, Plant physiology, Primary productivity, River transport.

A model can be used to illustrate the role of plants in the global carbon budget, with emphasis given to questions about the interaction of terrestrial vegetation and the atmosphere. The model is used to formulate four hypotheses dealing with the role of plants in the global carbon budget. These are:

(1) perturbed plant-dominated ecosystem are carbon sinks; (2) all terrestrial ecosystems, if left undisturbed are natural sinks of atmospheric undisturbed, are natural sinks of atmospheric carbon; (3) human land use causes the biota to be a carbon, (5) Indian I and use causes the olivate ocea-carbon source; and (4) higher carbon dioxide con-centrations in the atmosphere create a carbon sink by stimulating plant gross primary productivity. Current understanding of the global carbon budget Current understanding of the global carbon budget indicates that the budget does not balance unless an unrecognized sink of carbon is operating in the ocean or in the vegetation. Known sources of atmospheric carbon (burning of fossis fuels, 5.3 PgC/yr) and clearing of tropical forests, 1.3 PgC/yr) and clearing of tropical forests, 1.3 PgC/yr) are 1.6 PgC/yr higher than known sinks (PgC/yr), and atmosphere, 3 PgC/yr). However, plant communities that appear to be 'undisturbed' and thus assumed to be neutral with respect to carbon exchange with the atmosphere, may sequester up to 100 gC/sq m/yr in soil, wood and through river transport. If this rate of uptake actually occurs over a significant land area, the carbon budget of the world may become more balanced. More research is needed in tropical ecosystems before a full understanding of the global carbon cycle can be achieved. (See also W91-11066) (Author's abstract)

DETERMINATION OF TRACE LEVELS OF SULPHATE IN WATER USING FLOW-INJECTION AND IN-LINE PRECONCENTRATION. Tecator A.B., Hoganas (Sweden). M. Karlsson, J. A. Persson, and J. Moeller. Analytica Chimica Acta ACACAM, Vol. 244, No.

1, p 109-113, March 1991. 2 fig, 1 tab, 14 ref.

Descriptors: \*Ion exchange, \*Mass spectrometry, \*Preconcentration, \*Sulfates, \*Trace levels, \*Water analysis, Analytical methods, Anions, Cations, Pollutant identification, Sample preparation,

Sulfate is preconcentrated on a strong anion-exchange resin and determined using the effect of sulfate ions on the complexation of methylthymol blue and barium. A computer-controlled flow-injection analyzer is used to automate the whole procedure. The resin has two functions: it preconcentrates sulfate and also separates sulfate from divalent cations that may interfere in the determination step. The system can handle 30 samples per hr and has a working range from 25 to 100 micrograms/L of sulfate. Lower detection limits can be obtained by changing the preconcentration condiobtained by changing the preconcentration condi-tions. The effect of both anionic and cationic interferents was studied. In the direct measurement of sulfate without preconcentration, the main interfe surface without preconcentration, the main interest-ence is from divalent cations competing with barium in binding to the methylthymol blue rea-gent. A cation exchanger placed in the sample line or in the manifold can minimize this interference. Cationic interferents can be totally removed using Cationic interferents can be totally removed using a preconcentration scheme and by adding a proper wash cycle using calcium. The effects of various amounts of chloride, nitrate, and phosphate anions were studied. The relative selectivities for HSO4(-), NO3(-), and Cl(-) to the AG 1-X8 resin are 85, 65, and 22, respectively, which means that higher concentrations of chloride than nitrate should be tolerated. For chloride, concentrations up to about 2000 mg/L had no effect on the sulfate sensitivity 2000 mg/L had no effect on the sulfate sensitivity whereas for nitrate only about 200 mg/L could be tolerated. The tolerance limit for phosphate is between 1 and 5 mg/L. This interference can be controlled to some extent by decreasing the pH in the samples prior to the preconcentrations. HYDROCHEMISTRY OF A GROUNDWATER-SEAWATER MIXING ZONE, NAURU ISLAND, CENTRAL PACIFIC OCEAN.

New South Wales Univ., Kensington (Australia). Centre for Groundwater Management and Hydro-

J. Jankowski, and G. Jacobson J. Jankowski, and G. Jacobson.

BMR Journal of Australian Geology & Geophysics BJAGDT, Vol. 12, No. 1, p 51-64, 1991. 17 fig,

Descriptors: \*Geohydrology, \*Groundwater chemistry, \*Hydrologic data, \*Islands, \*Karst hy-drology, \*Saline-freshwater interfaces, Brackish water, Dolomite, Marine geology, Mixing, Oceans, Saline water, Salinity, Seawater, Vadose water.

Nauru Island is a karstified dolomitic limestone island in the central Pacific Ocean. An investigation of the island's hydrogeology has recently been undertaken in order to assure water resources for land rehabilitation of a large surficial phosphate mine. The investigation proved a thin, discontinu-ous freshwater layer overlies a thick brackish water mixing zone. Groundwater samples were collected from wells and caves, and also obtained during drilling. In the mixing zone, groundwater salinity increases gradually downwards until seawater is encountered at about 70 m below sea bicarbonate-calcium-magnesium groundwaters evolve to seawater. Saturation indi-ces for particular carbonate minerals increase with ces for particular carbonate minerals increase with increased groundwater salinity. Supersaturation is achieved with dolomite at 300 mg/L total dissolved solids, with calcite at 5000 mg/L, and with aragonite at 6000 mg/L. As groundwaters in the mixing zone are saturated with dolomite there is potential for dolomitization, and this probably occurs at low proportions of admixed seawater. Open and closed system trends can be defined, based on the partial pressure of carbon dioxide.

# **Group 2K—Chemical Processes**

The open system, with lower partial pressure, comprises vadose waters, cave waters and the more saline mixing zone waters; in the latter, chemical evolution is controlled mainly by mixing with seawater. The closed system comprises the freshwater layer with low proportions of admixed seawater; its chemistry is controlled by ingassing of carbon dioxide and by dissolution and precipitation reactions. Theoretical calculations based on simple mixing between karst groundwaters and seawater are inadequate to describe actual chemi-cal processes, which change with the degree of mixing. GEOCHEMICAL EVOLUTION OF GROUND WATER IN SMITH CREEK VALLEY-A HYDROLOGICALLY CLOSED BASIN IN CENTRAL NEVADA, U.S.A.

Geological Survey, Carson City, NV.
J. M. Thomas, A. H. Welch, and A. M. Preissler.
Applied Geochemistry APPGEY, Vol. 4, p 493510, 1989. 16 fig. 5 tab, 52 ref.

Descriptors: \*Geochemistry, \*Groundwater chemistry, \*Groundwater quality, \*Smith Creek Valley, Aquifers, Bicarbonates, Calcite, Calcium, Cation exchange, Chemical precipitation, Chlorides, Dissolved solids, Evapotranspiration, Groundwater recharge, Infiltration, Mountain streams, Nevada, Playas, Sodium, Stream discharge, Weathering,

Smith Creek Valley is a hydrologically closed basin in which groundwater is recharged by sub-surface inflow from surrounding mountains and infiltration of streamflow into alluvial-fan deposits near the mountains. Groundwater is discharged by evapotranspiration from shallow groundwater areas in the central part of the basin. Dominant ions in the dilute recharge water are Na, Ca and HCO3. Dissolved solids concentration increases during flow through the basin-fill sediments, with Na becoming increasingly dominant. In the dis-charge area, a bare-soil playa surrounded by phreatophytic vegetation, groundwater salinity, domi-nated by Na and Cl, increases markedly. The main nated by Na and Cl, increases markedly. The main processes controlling the geochemical evolution of groundwater in the basin-fill aquifer were identified using major-ion chemistry, mass balance calculations, thermodynamic calculations, stable isotopes, and mineral identification. These processes are: (1) dissolution of volcanic tuff and tuff-derived basin-fill deposits; (2) cation exchange of Ca and Mg in the water for Na in clay minerals; (3) weathering of plagioclase to montmorillonite; (4) precipitation of zeolite minerals; (5) concentration of dissolved constituents by evapotranspiration; (6) dissolution of Cl and SO4 evaporative salts; and (7) precipitation of calcite. REFINEMENT OF THE COMBINATION EQUATIONS FOR EVAPORATION. National Oceanic and Atmospheric Administration, Princeton, NJ. Geophysical Fluid Dynamics

Lao. P. C. D. Milly. Surveys in Geophysics SUGEEC, Vol. 12, p 145-154, 1991. 1 tab, 13 ref.

Descriptors: \*Evaporation, \*Mathematical equations, Air temperature, Mathematical analysis, Mathematical studies, Performance evaluation,

Most combination equations for evaporation rely on a linear expansion of the saturation vapor pres-sure curve around the air temperature. Because the sme curve around the air temperature, because the temperature by several degrees, and because the saturation vapor pressure curve is nonlinear, this approximation leads to a certain degree of error in those evaporation equations. It is possible, however, to introduce higher order polynomial approximations for the saturation vapor pressure curve and to derive a family of explicit equations for evaporation, having any desired degree of accuracy. Under the linear approximation, the new family of equations for evaporation reduces, in particular cases, previously derived combination equations. Comparison of the linear and quadratic approximations leads to a simple approximate expression for the error associated with the linear case. Equations based on the conventional linear approximation consistently underestimate evaporation, sometimes temperature at the surface may differ from this consistently underestimate evaporation, sometimes by a substantial amount. An analytical, lumped parameter, solute mass bal-ance model is developed to define the concept of a groundwater flux ratio as it applies to topographi-cally closed basins in which evaporation exceeds precipitation. The presence or absence of glauber-ite, mirabilite, halite, bloodies, excluding and precipitation. The presence or absence or gautoer-tie, mirabilite, halite, bloedite, polyhalite and hexa-hydrite, caused by subtle changes in the ground-water seepage is illustrated using an example from the Southern High Plains of Texas and New the Southern High Plains of Texas and New Mexico. However, this model is general and is applicable with any solute composition including that of seawater and the use of surface rather than groundwater. Diffusion, advection, and density-driven flow are mechanisms by which solutes can escape to the groundwater from these closed hasing. The geochemical reaction computer proescape to the groundwater from these closed basins. The geochemical reaction computer program PHRQPITZ is used to document the effects of various flux ratios on the mineralogy and thickness of deposits. It was determined that groundwater flux ratios can have a profound effect on the suite of minerals that forms in an evaporative basin and that large thicknesses of only one or two minerals can be deposited under steady state conditions. Solute analyses used in conjunction with the tions. Solute analyses used in conjunction with the model can be used to screen prospective basins as well as to provide insights for exploratory drilling programs. (Author's abstract) W91-11438

EFFECT OF COASTAL SEA LEVEL FORCING ON INDIAN RIVER BAY AND REHOBOTH BAY, DELAWARE.

Delaware Univ., Newark. Coll. of Marine Studies.

Estuarine, Coastal and Shelf Science ECSSD3, Vol. 32, No. 3, p 213-229, March 1991. 6 fig, 1 tab, 14 ref. NOAA, Office of Sea Grant NA86AA-D-

Descriptors: \*Bays, \*Coastal environment, \*Dela-ware, \*Model studies, \*Sea level, \*Water level fluctuations, Coastal waters, Computer models, Indian River Bay, Pumping mode model, Reho-both Bay, Water level.

Previous studies have suggested that sea level and current variability in Indian River Bay and Reho-both Bay, Delaware are primarily forced by coast-al sea level fluctuations. A linearized frequencyal sea level fluctuations. A linearized frequency-dependent pumping mode model was developed to examine the response characteristics of the Indian River Bay-Rehoboth Bay system, and to assess the relative importance of the coastal forcing from the Indian River Inlet and the Lewes-Rehoboth Canal. The results indicated that the pumping mode model can adequately address the first-order response of the two bays. The results further indicate that sea level variabilities in the two bays are almost entirely caused by coastal forcing from the Indian River Inlet at both tidal and subtidal frequencies. The coastal forcing from the inlet also dominates the volume flux through the system at all frequencies, but the coastal forcing conveyed through the Lewes and Rehoboth Bay can generate up to 20% of the total volume transport at very ate up to 20% of the total volume transport at very low frequencies. The low-frequency volume flux low frequencies. The low-frequency volume flux through the canal, however, generates a flow through the entire system and produces minimal sea level response. The overall response of the two bays to coastal forcing depends strongly on the degree to which the two bays acts as an effective low-pass filter to preferentially damp out high-frequency tidal motions in Rehoboth Bay. Because of the coupled nature of the response, the ditch also exerts substantial influence on the response characteristics of Indian River Bay. (Author's abstract) stract) W91-10494

SEASONAL VARIATION OF BIOMASS AND PRODUCTION DYNAMICS FOR ABOVE AND BELOWGROUND COMPONENTS OF A SPAR-TINA ALTERNIFLORA MARSH IN THE EU-HALINE SECTOR OF PARANAGUA BAY (SE

Universidade Federal do Parana, Curitiba (Brazil).

Descriptors: \*Bays, \*Brazil, \*Cord grasses, \*Marsh plants, \*Primary productivity, \*Salt marshes, \*Seasonal variation, \*Wetlands, Biomass, Ecology, Growth, Mangrove trees, Paranagua Bay, Plant growth, Productivity.

The seasonal variation of biomass and the annual net primary production for aboveground and belowground components of Spartina alterniflora Loisel intermediate form were evaluated by harvest methods over a 14-month period in Paranagua Bay (SE Brazil). Belowground components were characterized by a larger biomass, ranging from 172 +/48 g/square m at the end of summer to 569 +/-211 g/square m in late spring. The biomass of live aboveground tissue was usually higher than dead tissue, ranging from 51 +/-21 g/square m in winter to 116 +/-36 g/square m in summer. The overall mean root to shoot ratio was 4.8, ranging from 1.7 in summer to 8.5 in late spring, reflecting storage and translocation events. Net belowground primary production was 358 g/square m/year, largely exceeding aboveground production, which ranged from 101 to 179 g/square m/year, depending on how data were handled. Turnover of above and belowground material, expressed by a production to maximum biomass ratio, was fast, ranging from 0.66 to 1.52 years. In comparison with temperate Spartina marshes, the low productivity and low biomass of marshes of the high-energy sector of Paranagua Bay are probably a result of different growth strategies, high salinities and fast sediment accretion, which usually lead to their ultimate replacement by mangroves. (Author's abstract)

# IODINE CHEMISTRY IN THE WATER COLUMN OF THE CHESAPEAKE BAY: EVIDENCE FOR ORGANIC IODINE FORMS.

Delaware Univ., Lewes. Coll. of Marine Studies. G. W. Luther, T. Ferdelman, C. H. Culberson, J. Kostka, and J. Wu.

Estuarine, Coastal and Shelf Science ECSSD3, Vol. 32, No. 3, p 267-279, March 1991. 3 fig, 2 tab, 24 ref. NSF grants OCE-8696121, OCE-8916804, and OCE-8541747.

Descriptors: \*Chesapeake Bay, \*Iodides, \*Iodine, \*Water chemistry, Anoxic conditions, Bays, Oxygen, Primary productivity, Sulfur compounds, Water pollution, Water quality, Water sampling.

During the summer of 1987, Chesapeake Bay water samples were collected for the inorgan iodine species: iodide (by cathodic-stripping square-wave voltammetry) and iodate (by differential pulse polarography); and total iodine (by hypo-chlorite oxidation of the seawater sample to iodate). The difference between the sum of the inorganic iodine species and the total iodine was significant for about one-third of the samples collected from the Bay. Thus, in these samples, a third (or more) new form of iodine was present. These samples were primarily from oxygen-saturated surface waters of high biological activity (primary productivity and bacterial processes). This new face waters or ingn biological activity (primary productivity and bacterial processes). This new form can make up as much as 70% of the total iodine. Waters containing low oxygen concentrations showed less of this new form of iodine whereas anoxic and sulfidic bottom waters contained only iodide. This new form of iodine is organic in nature and probably non-volatile. It may organic in nature and protoatory non-votature. It may reside in the peptide and humic fractions. Only reduced iodine (iodide and organic iodine) was detected in waters from the northern section of the Bay, whereas only iodide and iodate were detected in the southern section of the Bay. In only two samples were iodide, iodate and the new form of iodine found to coexist. Iodide and organic iodine are probably cycled in the surface waters of the northern section of the Bay via a combination of biogeochemical and photochemical processes which produce the reactive intermediates, molecular iodine and hypoidous acid. These react quickly with reduced inorganic and organic compounds to maintain the reduced forms of iodine in the water column. Only total iodine is conservative through-out the estuary. The inorganic iodine forms can be used as geochemical tracers. (Author's abstract) W91-10496

MACROALGAL-SEDIMENT NUTRIENT INTERACTIONS AND THEIR IMPORTANCE TO MACROALGAL NUTRITION IN A EUTRO-PHIC ESTUARY.

Western Australia Univ., Nedlands. Centre for Water Research.

P. S. Lavery, and A. J. McComb.
Estuarine, Coastal and Shelf Science ECSSD3,
Vol. 32, No. 3, p 281-295, March 1991. 9 fig, 1 tab,
25 ref.

Descriptors: \*Algae, \*Algal growth, \*Cycling nutrients, \*Estuaries, \*Eutrophic estuaries, \*Nutrients, \*Sediment-water interfaces, Ammonium, Eutrophication, Nitrogen, Nutrient transport, Oxygen, Phosphates, Seasonal variation, Sediment analysis, Water quality.

The potential for algal banks to influence water quality and sediment nutrient flux was examined through laboratory experiments and in situ monitoring of algal banks. Loose macroalgal banks displayed seasonal changes in tissue nutrient concentrations suggesting a strong dependence on water column nutrients. These banks fail to generate conditions suitable to sediment nutrient release. Dense banks generated low oxygen conditions in the inter-algal water (0-1 mg/L), corresponding to zones of high, and relatively stable, phosphate and ammonium concentrations (up to 96 microgram/L PO4-P and 166 microgram/L NH4-N). Laboratory experiments confirmed that macroalgal banks can generate reducing conditions at the sediment surface, regardless of the aeration regime, through the decomposition of macroalgal tissue. Platinum electrode potentials as low as -200 millivolts were recorded in the inter-algal water. In such banks, redox-dependent sediment nutrient release and anaerobic accumulation of nitrogen accounted for inter-algal nutrient concentrations of over 60 microgram/L phosphate and 800 microgram/L ammonium. The generation of reducing conditions in inter-algal water required 7 days of still conditions and so this mechanism of nutrient generation is unlikely to be important in winter, when strong winds frequently shift the algal banks. It is suggested that in summer this mechanism may provide a source of nutrients to dense algal banks, supplementing reserves stored in winter. (Author's abstract)

#### FIRST-ORDER ORGANIC CARBON BUDGET IN THE ST LAWRENCE LOWER ESTUARY FROM 13C DATA.

Quebec Univ., Montreal.
M. Lucotte, C. Hilliaire-Marcel, and P. Louchouarn.
Estuarine, Coastal and Shelf Science ECSSD3, Vol. 32, No. 3, p 297-312, March 1991. 7 fig, 2 tab, 36 ref.

Descriptors: \*Estuaries, \*Isotope studies, \*Organic carbon, \*Sediment transport, \*St Lawrence Estuary, Algal blooms, Carbon, Particulate matter, Phytoplankton, Seasonal variation, Zooplankton.

Carbon isotope ratios and concentrations of suspended particulate matter and surface sediments of the Lower St. Lawrence Estuary were used to determine the seasonal fluxes of particulate organic matter to the estuarine floor. Light carbon particles brought by the St Lawrence River during spring freshet are carried to the intermediate and deep watermasses of the Lower Estuary until July. In contrast, heavy loads of 13C-enriched particles in the surface waters at the head of the Laurentian Channel are directly attributable to the early summer phytoplankton bloom or indirectly to the related zooplankton populations. Only small amounts of terrigenous particles from the turbid zone are still found in the early fall water column. All particles have a short residence time of a few days within the St Lawrence Estuary, limiting most seaward export. The surface sediments of the Lower Estuary have an average C-isotope composition of -22.4 parts per thousand. Using a simple two-components 13C-missing equation, this value represents 43 +/-8% of terrigenous and 57 +/-8% of marine particulate organic carbon. A first-order carbon budget was then derived from published sedimentation rates and primary production

estimates. About 75% of the terrigenous particulate organic matter introduced in the Upper Estuary is deposited within the limits of the Lower Estuary. Simultaneously, the equivalent of less than 30% of the annual phytoplanktonic carbon production in the Lower Estuary reaches the estuarine floor, mostly under the form of copepod fecal pellets. Over 70% of the photosynthesized carbon is biodegraded and recycled in the water column. (Author's abstract)

#### MANAGING OREGON'S ESTUARINE RE-SOURCES LANDS.

Oregon State Univ., Corvallis. Dept. of Geosciences.

P. L. Jackson. Journal of Soil and Water Conservation JSWCA3, Vol. 46, No. 1, p 23-26, January/February 1991. 2 tab, 2 fig, 17 ref.

Descriptors: \*Coastal zone management, \*Estuaries, \*Oregon, \*Wetlands, Coasts, Land use, Marshes, Restoration, Water law, Water policy, Wetland mitigation.

Resource planning is a major feature of Oregon's coastal zone management program. Estuarine mitigation has become an important phase in the planning and management of the state's coastal wetlands. The preservation and conservation of important estuarine habitat is balanced with water-related development through a coordinated program of local comprehensive planning, land use regulation, and waterway alteration laws. As part of this program, mitigation banking is used to maintain the integrity of estuarine ecosystems by restoring or enhancing substitute habitat where planned development would otherwise result in the loss of resource lands. Estuarine mitigation has received widespread attention as a means of resolving some of the problems inherent in balancing conservation and development in coastal wetlands. The idea of creating or restoring substitute habitat in exchange for habitat lost to development has intuitive appeal. Clearly, mitigation is not viewed as the complete solution to the wetlands conversion issue. Marsh restoration and creation technology has not progressed to the point of certainty of results. Recognizing these issues, the Oregon coastal zone management program relies on mitigation as a final requirement at the end of an extensive decision-making process. (Mertz-PTT)

On the Seto Inland Sea (SIS), westerly winds generally prevail, and complex land and sea breezes occur, due to the land morphology. The region has less precipitation and more sunshine than any other in Japan. Sea fogs occur from March to August. River discharge is greater in the eastern part of the SIS. These meteorological and

#### **Group 2L—Estuaries**

oceanographic factors control water mass genera-tion, diffusion of pollutants, and biological activi-ties in the SIS. Mean eastward water transport occurs via westerly winds. Generally, tidal cur-rents predominate, especially in straits, where cur-rents are rapid and vertical mixing is strong. The sea level is highest in Bisan Seto of the SIS, where sea surface temperature and salinity are relatively low. Bisan Seto appears to be the boundary between the eastern and western areas of the SIS. The nutrient concentration in the SIS increased between the 1930's and 1970's, but remained level oetween the 1930s and 1970s, but remained level since then. Water exchanges between the SIS and the Kuroshio occur in Bungo Channel and Kii Channel. In Kii Channel, the easternmost of the SIS, the coastal water appears to flow offshore in the upper layer, and the modified Kuroshio water appears to flow into Osaka Bay in the lower layer, as determined by observed water temperature, sa-linity, and dissolved oxygen profiles. OUTFLOW AND THREE-DIMENSIONAL SPREADING OF RIVER WATER IN EN-CLOSED BAY.

Osaka Univ. (Japan). Dept. of Civil Engineering. K. Nakatsuji, N. Yamamoto, and K. Muraoka. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 31-35, 1991. 5 fig, 7 ref.

Descriptors: \*Bays, \*Dispersion, \*Mathematical models, \*Model studies, \*Path of pollutants, \*Rivers, \*Stream discharge, Coastal waters, Gravity flow, Osaka Bay, Plumes, Pressure distribution, Satellite technology, Water quality, Yodo River.

Physical processes of outflow and gravitational spreading of the Yodo River in the Osaka Bay can be explained by means of a three-dimensional, primitive equation model. The river water spreads primitive equation mode. The river water spreads out over the sea water, controlled by horizontal pressure gradients resulting from density differ-ences. On a horizontal length scale on the order of the Rossby deformation radius, the earth's rotation exerts a strong influence on river water outflow behavior. The results of the model predictions compare well with the satellite infrared image. Model results indicate that the deformation of the outflow pattern and the formation of a coastal current are unique features of river plume spreading in cases of high river discharges. Since the ing in cases of high river discharges. Since the water quality of enclosed bays depends largely on the input of pollutants through rivers, understanding of the outflow dynamics of river plumes is important. (Author's abstract) W91-10525

WATER EXCHANGE AND TRANSPORT OF MATTER IN THE SETO INLAND SEA. Ehime Univ., Matsuyama (Japan). Dept. of Ocean

eering. H. Takeoka. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 41-44, 1991. 3 fig. 3 tab, 6 ref. Descriptors: \*Coastal waters, \*Japan, \*Mathemati-cal models, \*Model studies, \*Nutrient transport, \*Organic loading, \*Seto Inland Sea, \*Water chem-istry, \*Water exchange, Channels, Flow discharge, Nitrogen, Nutrient concentrations, Residence time, Rivers, Upwelling, Vertical mixing.

Enclosed coastal seas are regarded as transport systems with a flux of concentrated matter and a standing stock in the coastal sea. Mechanisms de standing stock in the coastas sea. Mechanisms de-termining the average residence time (ART) of the nitrogen in the Seto Inland Sea, Japan, are exam-ined by using a simple numerical model. Since the Seto Inland Sea is a long channel, it can be simplified horizontally to a one-dimensional channel of 500 km long. The flow in the channel is directed outward in the upper layer and inward in the lower layer. Since the river discharge is larger in the eastern part of the inland sea, the center of the the eastern part of the initial sea, the center of the upwelling is assumed to be located in the eastern part. The ART of the nitrogen is larger than that of the riverine water by about twice, due to the coupled effect of the flow having a vertical shear and biochemical processes. Strong vertical mixing at the straits reduces the ART of the nitrogen. Mixing through Naruto Strait also effectively reduces the ART of the nitrogen. The coupled effect of the flow's vertical shear and the biochemical processes makes the ART of the nitrogen layer larger than that of the riverine water or of other permanently dissolved matter. Strong vertical mixing at the straits reduces the ART of the nitrogen. Mixing through Naruto Strait also effectively reduces the ART of the nitrogen. (Brunone-PTT)

The management of coastal seas requires scientific knowledge to link inputs to resulting concentra-tions; to distinguish between natural variability and tions; to distinguish between natural variability and man's impact; and, to predict long-term trends. This knowledge incorporates movement and dis-persion of both water and sediments, partitioning of contaminants between dissolved and particulate phases, and successive exchange processes between river/estuary/coastal zone/sea/ocean and between sea/seabed and sea/atmosphere. The UK is presently midway into a five-year, fifteen million pounds oceanographic research program in the North Sea involving the development of numerical models, systematic observations and fundamental research to fill gaps in basic knowledge. The program will proceed through three stages, simulating physical, biological, chemical and sedimentological

parameters over the well-defined seasonal cycle, over inter-annual variations, and for long-term trends. Long-term data sets are vital for such protrends. Long-term data sets are vital for such programs, using systematic marine monitoring programs involving combinations of remote sensing, sea-truth moorings, and coastal stations. This program will be extended to consider the contribution to and effect from global pollution, specifically possible greenhouse effects, such as a rise in mean sea level and meteorological changes. The wide-spread impact of such phenomena emphasizes the necessity for international cooperation in all aspects of these studies. (Author's abstract) W91-10531 W91-10531

INTRODUCED SPECIES--RESOURCE OR THREAT IN BRACKISH-WATER SEAS: EXAM-PLES FROM THE BALTIC AND BLACK SEA. Abo Akademi, Turku (Finland). Dept. of Biology.

E. J. Leppakoski.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 219-223, 1991. 1 fig, 26 ref.

Descriptors: \*Baltic Sea, \*Black Sea, \*Brackish water, \*Coastal areas, \*Introduced species, Bivalves, Ecosystems, Inland waterways, Invasions, Life cycles, Mollusks, Phaeophyta, Polychaetes, Population dynamics, Species diversity.

Species introductions into marine and brackish-water systems were not studied systematically prior to the 1950's. Enclosed seas, such as the Black Sea and the Baltic, can be regarded as dis-junct 'brackish-water islands', with an impover-ished flora and fauna, locked in by land and isolat-ed from other major brackish-water bodies by physical (ocean and land) barriers. The four suc-cessive stages of invasions are arrival, establish-ment, spread and persistence. Hundreds of intro-duced species have arrived (many of them by merduced species have arrived (many of them by mere chance) into the brackish Black and Baltic Seas, or their coastal ecosystems, as planktonic larvae in ballast water tanks, as sessile organisms attached to hulls, or as benthic stages living in (or on) the sediment settled on the bottom of the tanks, or have been introduced intentionally. Most of them have been unable to maintain a self-sustaining population and thus only small numbers of these spe-cies have become established in these seas, and still fewer have been able to spread on a sea-wide basis. Mya arenaria has persisted in northwest European waters for 300 to 400 years, in the Black Sea for waters for 300 to 400 years, in the Biack Sea for not more than 30 years to the present. Balanus improvisus has been very successful in the Baltic Sea since the late 1800's. Examples of the latest newcomers from northeast European seas into the Baltic are the American jackknife clam Ensis directus, the spionid polychaete Merenzelleria viridis, and the brown alga Sargassum muticum. An example from the Black Sea of recent introductions is the bivalve Cunearca cornea. Since all vessels destined for any Baltic or Black Sea harbor have to pass fully marine waters with oceanic salinities, a relatively simple and cheap method of seducing relatively simple and cheap method of reducing the risk of unintentional introductions of estuarine species into these enclosed brackish-water seas would be a mid-ocean exchange of ballast water en-route. TOWARD ENVIRONMENTAL PLANNING FOR EAST ASIAN ESTUARIES: JAPANESE AND CHINESE ENCLOSED BAYS.

Osaka Geijutsu University, Department of Environmental Planning, Osaka Prefecture, 585 Japan. H. A. Shapiro. Marine Pollution Bulletin MPNBAZ, Vol. 23, p

363-368, 1991. 6 fig, 4 tab, 10 ref.

Descriptors: \*China, \*Coastal zone management. Peconomic development, \*Environmental impact, \*Environmental protection, \*Estuaries, \*Japan, Ecosystems, Environmental impact statement, Hazards, Human population, Path of pollutants, Planning, Primary productivity, Water pollution.

East Asia consists of several nations each in different stages of economic development, from developing, to newly developed, to advanced industrial. In almost every case, the coastal zones of these nations are highly biologically productive. However, at the same time, they are vulnerable to natural hazards, with enclosed coastal waters particularly vulnerable to pollution. Tokyo Bay, one of Japan's foremost important and productive estuarine ecosystems, is located in the Kanto area of eastern Japan. Hazard-related criteria, such as earthquake vulnerability, flood vulnerability, marine explosions, and fire, were compiled. Aesthetically and culturally valuable areas were mapped. Finally natural and human-health-related criteria were all mapped at a common scale. Water-related criteria were combined to identify areas where land and East Asia consists of several nations each in differmapped at a common scale, water-related criteria were combined to identify areas where land and water have mutually strong impacts on each other. In order to protect the quality of the environment of these areas, especially the pollution and hazard-vulnerable, highly biologically productive en-

closed coastal areas, an environmentally sensitive approach to sustainable development appears to be a fundamental necessity. (Brunone-PTT) W91-10565

NON-REGULATORY APPROACHES TO MAN-AGEMENT OF COASTAL RESOURCES AND DEVELOPMENT IN SAN FRANCISCO BAY. California State Coastal Conservancy, Oakland. P. Grenell.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 503-507, 1991, 6 ref.

San Francisco Bay is the largest coastal water body in California. Many large, enclosed water bodies in other countries are likely to experience some of the Bay's problems. The management of the Bay's coastal resources may be relevant for other nations now facing similar problems. The Bay Area's resources are regulated by three main

#### **Group 2L—Estuaries**

agencies: the San Francisco Bay Conservation and Development Commission, the United States Army Corps of Engineers, and the regional water quality control boards. In addition to these, numerous others exercise other limited regulatory, planning, or advisory functions. In particular, the California State Coastal Conservancy's (CSCC) experience as a non-regulatory problem-solving agency may be pertinent to situations which either have may be pertinent to situations which either have similar complex regulatory systems as the Bay Area, or which face problems not amenable to regulatory solutions. The CSCC was created in regulatory solutions. The CSCC was created in 1973 with a broad mandate: to protect, restore and enhance coastal resources. The CSCC has been instrumental in protecting diked wetlands and agriculture, resolving multiple-use conflicts, experimental uses of treated wastewater in marsh enhancement, providing public access to the Bay Shore, and restoring the Bay's urban waterfronts. Descriptors: \*Chlorophyll, \*Coastal waters, \*Eutrophication, \*Japan, \*Nutrients, Comparison studies, Human population, Imari Bay, Inorganic nitrogen, Kagoshima Bay, Seasonal variation.

Bays in western Kyushu face the open sea, and Bays in western Kyushu face the open sea, and have unique characteristics. Fukuoka Bay is surrounded by a big city, Imari Bay holds a large number of mariculture sites, and Kagoshima Bay is divided into two parts (a closed inner part and a semi-closed outer part). Data from Fukuoka indicated a relationship between high chlorophyll levels and low chlorophyll and high dissolved inorganic nitrogen in summer, and low chlorophyll and high dissolved. summer, and low chlorophyll and high dissolved inorganic nitrogen in the winter. Data from Imari Bay varied greatly. In Kagoshima Bay, dissolved inorganic nitrogen concentrations were similar beinorganic nitrogen concentrations were similar oc-tween the two parts, but chlorophyll values were distinctly higher in the inner part. The composition of nitrogen varied seasonally. These results were compared with data collected world-wide, and the results suggested that coastal water may increase cutropnication from equivalent dissolved inorganic nitrogen levels. These levels are probably caused by some organic enrichment from human activities. Characteristics of each bay seem to be consistently influenced by their social backgrounds and topographical features. (Author's abstract) W91-10595 eutrophication from equivalent dissolved inorganic

SEDIMENT TRANSPORT ON THE FORE-

Descriptors: \*Accretion, \*Beach profiles, \*Beaches, \*Coastal waters, \*Sediment transport, \*Sedimentation, \*Shorelines, \*Spain, Erosion, Las Palmas, Tidal effects, Tidal range.

Beach face profiles have been measured at El Hombre Beach (Las Palmas, Spain), a typical pocket beach 200 m in length and 100 m in width, between December 1988 and December 1989.
Changes in beach profiles have been related to the standard deviation, which is used to fix the berm position. Sand volume changes are related to the maximum tidal range. The central beach sector showed an end erosion of 50 cubic m/m. From the results, longshore transport appears to be very important on the beach. An increase in tidal range often corresponds with the erosion rate, and a decrease in tidal range results in accretion. (Brunone-PTT) W91-10599

CONSTRUCTION OF ARTIFICIAL SEAWEED BED ACCOMPANIED WITH THE RECLAMATION FOR UNIT NO. 3 OF IKATA POWER

Shikoku Research Inst., Inc., Takamatsu (Japan). H. Yokouchi, R. Yamamoto, and Y. Ishizaki. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 719-722, 1991. 10 fig.

Descriptors: \*Algae, \*Aquatic habitats, \*Artificial substrates, \*Fish, \*Japan, \*Mollusks, Baseline studies, Environmental monitoring, Flow rates, Land reclamation, Powerplants, Species diversity, Transparency.

Seaweed beds provide good habitats for many organisms, including fish and shellfish, in Japan. Recently, natural seaweed beds have been reduced. due to the effects of seashore reclamation and marine pollution in the Seto Inland Sea. Construc-tion of artificial seaweed beds was proposed, as an environmental preservation measure, when Unit No. 3 of the Ikata Power Station was planned. Baseline studies, monitoring at 5, 10, 15, and 20 m depths, had been carried out for five years. The mean velocity of the water current was 0.07 to 0.16 m/sec at all monitored depths, and the transparency was 9.2 to 10.1 m. Sixty to eighty species of seaweds are found in the study area, and the species diversity on the artificial mounds was comparable to that of natural seawed beds. Based on the results, two mounds were piled in front of the station, and have provided comparable coverage to that of natural seawed beds, as predicted. (Brunone-PTT) W91-10603

SUCCESSION OF BENTHIC ASSEMBLAGES IN WILD BIRD PARK, A SANCTUARY ESTAB-LISHED ON RECLAIMED LAND IN OSAKA

Osaka City Inst. of Public Health and Environ-

Osaka City Inst. of Public Health and Environ-mental Sciences (Japan). H. Yokoyama, T. Umehara, and K. Oda. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 739-742, 1991. 2 fig. 5 ref.

Descriptors: \*Aquatic habitats, \*Japan, \*Land reclamation, \*Osaka Port, \*Species diversity, \*Waterbirds, Amphipods, Biomass, Comparison studies, Intertidal areas, Lagoons, Seawater, Tidal flats.

The population of benthic animals and environmental parameters were surveyed in three areas (Marsh A, Marsh B, and the Lagoon) of Wild Bird Park, an area constructed on reclaimed land in Osaka Port, Japan, to obtain data to aid in increasing the numbers of prey organisms for shorebirds. ing the numbers of prey organisms for shorebirds. In Marsh A, formed by standing rainwater, marine benthic organisms intruded as seawater was introduced. In Marsh B, created by the pumping in of seawater, intertidal gammarids disappeared and chironomid larvae dominated as freshwater gradually replaced the seawater. In the Lagoon, connected to the sea by ducts, a large biomass and high species diversity were noted, but large, intertidal animals were scarce. A comparison with the results of surveys made on the tidal flat at the results of surveys made on the tidal flat at the mouth of Onosato River suggests that natural features should be introduced into Wild Bird Park for future development of an intertidal community. (Author's abstract)

FLOW CONTROL TECHNOLOGY FOR EN-HANCEMENT AND DIVERSE USE OF THE MARINE ENVIRONMENT.

Government Industrial Research Inst., Chugoku, Kure (Japan).

In the Seto Inland Sea, large red tide blooms and water mass anoxia exist, due to water stagnancy. Improvement of water mass movements may be made possible in a tidal basin through topography made possible in a tidal basin through topography change and construction efforts. The development of flow control technology is required to repair deteriorated water quality environments and to create appropriate physical flow fields which maximize the diverse use of coastal waters. Studies were carried out with the Seto Inland Sea hydrau-

#### Estuaries-Group 2L

lic model containing the Osaka and Beppu Bays. The effects of topography changes at the mouth of the bay and on the sea floor for Osaka Bay and a dike construction at the mouth of Beppu Bay were surveyed for water mass exchanges, circulation, and mixing and advection of the river water discharged into those how. charged into these bays. These measures effectively alter the balance and pattern of circulation, helping to improve water movement in the stagnant regions of the basin. (Author's abstract) W91-10607

IMPROVED POLICY INSTRUMENTS FOR MANAGEMENT OF ENCLOSED COASTAL SEAS AND ESTUARIES: THE CHESAPEAKE

SEAS AIM ESTABLES

BAY, USA.

Maryland Univ., Solomons. Center for Environmental and Estuarine Studies.

J. H. Cumberland.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 773-777, 1991. 1 tab.

Descriptors: \*Chesapeake Bay, \*Coastal waters, \*Coastal zone management, \*Economic aspects, \*Environmental policy, \*Estuaries, Environmental effects, Land use, Nonstructural alternatives, Policy making, Public participation, Public policy, Regulations, Resource allocation, Taxes, Water pollution control, Water quality standards.

The most coherent and systematic critique of current environmental policy instruments has come from economics, which has provided detailed tech-nical recommendations for policies utilizing eco-nomic incentives to pursue efficiency objectives. The major focus of environmental economics has been the design of ever more refined policy instru-ments for the efficient reduction of pollution exter-nalities. In many cases, economic incentives, such names. In many cases, economic incentives, such as pollution taxes, or an equivalent set of transferable, marketable emission permits can provide economic methods for improving water quality, usually at lower total social costs than can traditional regulatory methods. Pollution emitters usually sefer the equipment of the provider of prefer the regulatory system, because costs to them are much less than in incentive systems. Zoning can be an efficient means of controlling land use, but suffers some disadvantages from a public but suffers some disadvantages from a puone choice point of view. Compensating owners for land takings may lead to more efficient resource allocations. Marginal cost pricing on waterfront development could provide more accurate signals about the full social costs of waterfront development and provide incentives for reducing popula tion density in sensitive areas. Economic and posi-tive externalities would often be greater and environmental losses and negative externalities smaller if industrial and commercial development were if industrial and commercial development were shifted to inland areas, protecting sensitive water-front areas for recreational and low-density uses. Present management policies cannot save marine resources from immutable laws of thermodynamics and entropy, but environmental economics strengthened by insights from physical sciences, biological sciences, and from the study of public choice can assist in the search for more effective management policies. STUDIES OF DISSOLVED CARBOHYDRATES (OR CARBOHYDRATE-LIKE SUBSTANCES) IN AN ESTUARINE ENVIRONMENT.

IN AN ESTUARINE ENVIRONMENT.
Universite de Bretagne-Occidentale, Brest (France). Lab. d'Oceanographie Chimique.
W. Senior, and L. Chevolot.
Marine Chemistry MRCHBD, Vol. 32, No. 1, p 19-35, January 1991. 5 fig. 2 tab, 39 ref.

Descriptors: \*Analytical methods, \*Carbohydrates, \*Dissolved organic carbon, \*Estuarine environment, \*Seasonal variation, Bay of Brest, Elorn estuary, France, Organic matter, Salinity.

Variations in concentrations of dissolved sugars variations in concentrations of dissolved sugars were studied along the salinity gradient of a small estuary (Elorn, Bay of Brest, France) from February 1985 to January 1986. Total dissolved carbohyary 1983 to January 1986. Total dissolved carbony-drates (TDCHO) and dissolved monosaccharides (MCHO) were measured by methods that cannot distinguish between carbohydrates and carbohydrate-like substances; consequently, these methods probably do not closely reflect biologically available pools of carbohydrates. In the river, TDCHO

and MCHO values ranged from 230 to 970 micrograms C/l and from 75 to 450 micrograms C/l respectively. In the estuary, TDCHO and MCHO respectively. In the estuary, TDCHO and MCHO
were usually lower; they varied respectively from
20 to 570 micrograms C/1 and from 0 to 180
microgram C/1. In June, some TDCHO values
were much higher, probably because some polysaccharide was produced at this time by phytoplankton excretion or lysis. The relationship between Cl concentration and TDCHO was dependent on the seasons. TDCHO was conservative in
whater and early reprise TDCHO and autumn, winter and early spring. TDCHO and DOC concentrations were fairly well correlated during the same period. Similar results were previ-ously reported. MCHO and TDCHO concentrations were well correlated throughout this study except in June. It was concluded that most dised carbohydrates were linked to a conservative fraction of the organic matter in periods of low biological activity, whereas newly biosynthe-sized carbohydrates were responsible for non-con-servative behavior. TRACE METAL INTERACTIONS WITH MARINE PHYTOPLANKTON.

National Marine Fisheries Service, Beaufort, NC. Beaufort Lab. W. G. Sunda.

Biological Oceanography BOJODV, Vol. 6, No. 5/6, p 441-442, 1988/9. 10 fig, 3 tab, 92 ref.

Descriptors: \*Algal physiology, \*Nutrients, \*Phytoplankton, \*Toxicity, \*Trace metals, \*Water pollution effects, Chelation, Cobalt, Copper, Iron, Manganese, Metabolism, Nickel, Productivity,

Large spatial and temporal differences in both trace metal concentrations and chemical speciation in the sea have led to wide variations in biological availability of metals and their effects on phyto-plankton. Trace metals are usually taken up by algae via the formation of coordination complexes with specialized transport ligands in their outer membranes, and metal uptake is determined by the interplay between redox, complexation, or oxide interplay between redox, complexation, or oxide dissolution reactions of metals in seawater and ligand-exchange reactions at these sites. Some metals, such as Cu and Zn, are heavily chelated by organic ligands in seawater, and their biological availability is determined by the concentration of free metal ions or of kinetically labile inorganic species (free ions plus inorganic complexes). Once inside cells, trace metals influence metabolism primarily as a consequence of the role of many of these metals (Fe, Mn, Cu, Co, Mo, Ni) as essential cofactors in metallocarymes. Trace metals also inhibit metabolism when they bind to the wrong metabolic sites including those normally occupied by other essential nutrient metal ions. The interactions of metals at the biomolecular level determine their overall effect on cellular rate processes, such their overall effect on cellular rate processes, such as growth, and on the productivity of the phytoplankton community as a whole. Evidence exists for limitation of algal productivity by soluble inorganic Fe concentrations and Mn:cupric ion ratios in certain regions of the sea. However, wide differ-ences exist among algal species in their require-ments for nutrient metals or in their sensitivity to toxic metals, and thus the predominant effect of trace metals may be on species composition of phytoplankton communities. The effects of metals on phytoplankton are reciprocal, and the phytoplankton community itself has a profound influ-ence on the concentrations and chemical speciation of trace metals in seawater, providing important biological feedback. WETLAND IMPOUNDMENTS OF EAST-CEN-TRAL FLORIDA

Florida Medical Entomology Lab., Vero Beach. J. R. Rey, T. Kain, and R. Stahl. Florida Scientist FLSCAQ, Vol. 54, No. 1, p 33-

Descriptors: \*Coastal environment, \*Florida, \*Mangrove swamps, \*Salt marshes, \*Wetland impoundments, \*Wetlands, Flooding, Insect control, Resources management, Waterfowl, Wildlife man-

Data on the physical characteristics, vegetation, geographic location, and areal coverage of the astal impoundments in east-central Florida were llected. There are 195 impoundments in the collected. collected. There are 195 impoundments in the region, covering over 16,000 ha of coastal wetlands. Vegetation in the impoundments is diverse; mangroves predominate in the southern impoundments while herbaceous halophytes predominate in the northern ones. Approximately 3,600 ha of these impoundments are unvegetated, whereas mangroves cover close to 4,000 ha and other halophytic species 4,300 ha. Management of the impoundments varies from none to complex schemes that address not only mosquito control problems but also natural resource and habitat quality interests. Nearly 4,500 ha of impounded wetlands in the Merritt Island National Wildlife Refuge are flood-Merritt Island National Wildlife Reruge are Hood-ed year-round for waterfowl management, whereas 2,857 ha are under Rotational Impoundment Man-agement. Improved management of the east central Florida impoundments will continue to be a high priority item for local scientists, resource managers, environmental regulatory agencies, and mos-quito control personnel. Although there will conquito control personnel. Although there will con-tinue to be a strong push for enhancing lagoon-impoundment connections, particularly in im-poundments that are totally isolated, the emphasis is now shifting from managing individual impound-ments to managing groups of impoundments as blocks so that complementary management strate-gies can be applied to different members of the block. ANNUAL BACTERIAL PRODUCTION IN RE-ANNUAL BACTERIAL PRODUCTION IN RE-LATION TO BENTHIC MICROALGAL PRO-DUCTION AND SEDIMENT OXYGEN UPTAKE IN AN INTERTIDAL SANDFLAT AND AN INTERTIDAL MUDFLAT. Bigelow Lab. for Ocean Sciences, West Boothbay

L. M. Cammen L. m. - Caumien.
Marine Ecology Progress Series MESEDT, Vol.
71, No. 1, p. 13-25, March 28, 1991. 10 fig. 1 tab, 50 ref. NSF grants EXPO80-11448, OCE-83-09406, and OCE-83-11281.

Descriptors: \*Algae, \*Bacterial productivity, \*Intertidal areas, \*Marine bacteria, \*Marine sediments, \*Mud flats, \*Sand flats, Benthic fauna, Organic matter, Oxygen uptake, Seasonal variation, Water temperature.

In order to investigate the controls of bacterial abundance and production in marine sediments, bacterial production determined by uptake of 3-Hbacterial production determined by uptake of 3-Hthymidine, microalgal production and sediment oxygen uptake was investigated monthly for 1 yr in two benthic systems, an intertidal mudflat and an intertidal sandflat. There was a closer coupling between these rates in the sandflat than in the mudflat that may have been due to the more dynamic nature of the sandflat. The parameters measured fell into two groups based on the similarity between their annual totals or mean abundances for the mudflat and for the sandflat. Although ior the mutitat and for the sanditat. Although microalgal biomass, gross production, and sediment oxygen uptake were similar for both areas, bacterial biomass, bacterial production, and sediment organic carbon were all 4-5 times higher in the mudflat than in the sandflat. Estimated annual turnovers of the bacterial population were 52 for the postulation. the sandflat and 59 for the mudflat. Temperature the sandlat and 59 for the mudlat. Temperature was the factor that had the greatest influence on bacterial production, explaining 55-57% of seasonal variation in specific growth rate. Bacteria appeared to respond to the increase in temperature in late winter-early spring more quickly than the rest of the sediment community; this would imply that

the input of organic matter to the benthos from an early spring bloom, occurring in colder waters, might result in a less efficient transfer of energy to the macrofauna, than would occur with a later the macrofauna than would occur with a bloom. (Author's abstract) W91-10865

ASSIMILATION OF METALS IN MARINE CO-PEPODS AND ITS BIOGEOCHEMICAL IM-PLICATIONS.

71, No. 1, p 37-43, March 28, 1991. 3 fig, 1 tab, 43 ref. NSF grant OCE 8810657.

Descriptors: \*Bioaccumulation, \*Biogeochemistry, \*Copepods, \*Geochemical cycles, \*Marine biology, \*Metals, \*Path of pollutants, Americium, Cadmium, Feces, Marine algae, Marine environment, Mercury, Plutonium, Radioisotopes, Zinc.

Laboratory experiments employing gamma-emit-ting radiotracers assessed the retention efficiency of ingested metals in the calanoid copepod Anoma-locera patersoni and the retention of excreted metals in fecal pellets. Adult copepods ingested the haptophyte Isochrysis galbana labeled with 109-Cd, 65-Zn, 203-Hg, 241-Am and 237-Pu at a rate of 3.79 mg algal C/g animal dry wt/h. Average re-tention efficiencies were 30% for Cd, 48% for Zn, 21% for He, 4.5% for Am, and 0.8% for Ph. Adv. 21% for Hg, 4.5% for Am, and 0.8% for Pu. Algal cells resuspended into unlabeled seawater retained cens resuspended into unaocied seawater retained metals to varying extent, with depuration curves conforming to a 2-compartment model; Cd was lost most rapidly. The fecal pellets produced by animals feeding on radioactive I. galbana lost essentially all of their 109-Cd, 65-Zn, 241-Am, and 237-Pu to unlabeled seawater within 1 d. 203-Hg was lost most slowly, again conforming to a 2 compartment model; its retention half-time was compartment model; its retention half-time was about 25 d in the slowly exchanging pool. Bacterial activity did not appear to have an effect on metal retention in the fecal pellet. The retention efficiencies suggest that Cd, Zn, and Hg should be recycled by copepods in surface waters as part of the organic cycle in the sea, while the transuranic elements should be defecated and removed from surface waters by sinking biogenic debris. (Ausurface waters by sinking biogenic debris. (Author's abstract) W91-10866

BALANCE OF NUTRIENT LOSSES AND GAINS IN SEAGRASS MEADOWS. Delta Inst. for Hydrobiological Research, Yerseke

M. A. Hemminga, P. G. Harrison, and F. Van

Marine Ecology Progress Series MESEDT, Vol. 71, No. 1, p 85-96, March 28, 1991. 1 fig, 3 tab, 106

Descriptors: \*Cycling nutrients, \*Marine sediments, \*Sea grasses, \*Wetlands, Biomass production, Denitrification, Diffusion, Foraging, Leaves, Marine environment, Nitrogen fixation, Sedimenta-

Seagrasses abound in the dynamic environment of shallow waters. From the often high annual bio-mass production it can be deduced that seagrass meadows have high requirements for inorganic nutrients, although the nutrient demands will be met to some extent by internal recycling. A series of processes lead to nutrient losses from the sea-grass bed. Export of leaves and leaf fragments with currents, leaching losses from photosynthetically active leaves and from senescent and dead plant material, and nutrient transfer by mobile foraging animals, are processes specific to seagrass mead-ows. In addition, the nutrient losses are aggravated by 2 processes commonly occurring in marine sediments: denitrification and diffusion of nutrients The persistence in time of most seagrass meadows points to an existing balance between nutrient losses and gains. Three processes losses and gains. Three processes may contribute to the replenishment of nutrients: nitrogen fixation, sedimentation and nutrient uptake by the leaves. Nitrogen fixation undoubtedly is important, but

continued biomass production requires other nutrients as well. Crucial contributions, therefore, must come from sedimentation and/or leaf uptake. The concept of the seagrass meadow as an open system, with nutrient fluxes from and to the system varying in time, allows for imbalances between nutrie losses and gains. It is suggested that these imbal-ances may contribute to fluctuations in annual seagrass biomass production. (Author's abstract) W91-10867

COULOMETRIC MEASUREMENT OF PRI-MARY PRODUCTION, WITH COMPARISON AGAINST DISSOLVED OXYGEN AND 14-C METHODS IN A SEASONAL STUDY.

Bedford Inst. of Oceanography, Dartmouth (Nova Scotia). Biological Oceanography Div.

Marine Ecology Progress Series MESEDT, Vol. 71, No. 1, p 97-102, March 28, 1991. 4 fig, 1 tab, 19

Descriptors: \*Coulometry, \*Nova Scotia, \*Photo-synthesis, \*Phytoplankton, \*Primary productivity, Analytical methods, Carbon dioxide, Carbon radioisotopes, Dissolved oxygen, Marine environ-

Consumption of CO2, as measured by direct coulometry in light and dark bottles, was used to estimate the photosynthetic rate of natural assemblages of phytoplankton incubated in situ. A total of 30 experiments were made during a 12-month period in Bedford Basin, Nova Scotia. For comparison, simultaneous estimates of primary produc-tion were made on each occasion using both the light-and-dark-bottle oxygen method and the 14-C method. Primary production values fell in the range <1 to 50 mmol/cu m/d. Throughout this range, excellent agreement was found between primary production as estimated by the 14-C meth and gross primary production estimated by changes in dissolved CO2. Release of labelled carbon into solution accounted for 2-19% of total primary production as measured by the 14-C method, with the lower values occurring in the spring bloom period. When the carbon-based rewere compared with the oxygen-based ones, they agreed to within a mean apparent photosynthetic quotient (PQ) of 1.6. High apparent PQ's in winter are attributed to an overestimation of oxygen primary production and an underestimation of 14-C primary production. Direct coulometry offers considerable promise as a technique for measuring photosynthesis by phytoplankton. (Author's abstract)

The Hg burden and otolith characteristics of bluefin tuna caught in the Balearic Sea, northwest Mediterranean were studied in order to determine Mediterranean were studied in order to determine their population dynamics and gather additional information for the delineation of bluefin populations. The tissue Hg levels ranged widely. In juveniles the levels were high and significant, showing the dependence of Hg level on fish size. The amount of Hg increased notably in older fish but was poorly correlated to body weight. The otolith microstructure was vary variable, which only allowed the differentiation of growth phases from juvenile to adult. The microincrement width was very variable and probably a function of the time of year when it was deposited. Observations of increment width suggests that wide increments were deposited during favorable conditions, while thin increments corresponded to unfavorable periods (migrations, spawning, winter). The marginal thin increments corresponded to uniavoue periods (migrations, spawning, winter). The marginal otolith structures of giant fish show that the majority (55%) were actively growing during their migration. The formation of discontinuous structures in the otoliths might be related to the physiological status, spawning and migration. The otoliths corresponding to a lower Hg burden were characterized by a more uniform elemental composition (Na, Cl, Ca, Sr, Si, S, Al), while the high Hg burden fish showed more variability in their composition. The otolith elemental composition might reflect ambiotolin elemental composition might relect anoisent water, dietary differences or water temperature differences. This might suggest a more changing environment experienced by the high Hg body burden fish. These results are a first attempt to differentiate the two postulated tuna populations in the Mediterranean. (Sand-PTT)

SULFUR ENRICHMENT OF HUMIC SUB-STANCES IN A DELAWARE SALT MARSH SEDIMENT CORE. Delaware Univ., Newark. Coll. of Marine Studies. T. G. Ferdelman, T. M. Church, and G. W.

Geochimica et Cosmochimica Acta GCACAK, Vol. 55, No. 4, p. 979-988, April 1991. 7 fig. 5 tab, 49 ref. NSF grants OCE-8541757, OCE-8696121, and OCE-8916804.

Descriptors: \*Humic substances, \*Marine sediments, \*Organic matter, \*Salt marshes, \*Sulfur, Detritus, Pyrite, Spartina, Sulfur compounds.

equential extraction scheme, results, and pos-The sequential extraction scheme, results, and possible implications regarding the formation and distribution of solid-phase organic sulfur in salt marsh sediment is reported. Samples from 9 depths of the core of a Delaware Spartina alterniflora marsh sediment were sequentially extracted in a glovebox or glovebag under nitrogen atmosphere and in subdued light. Humic sulfur, operationally defined as the sulfur extracted with humic substances in 0.1 N NaOH solution, comprised up to 51% of the total sulfur inventory in the core. Pyrite sulfur was the next largest fraction, except at the near-surface sediments, where zerovalent sulfur concentrations were significant. X-ray photoelectron spectrosco-py indicated that the humic sulfur consists of sul-foxides or sulfones and, in a more reduced state, organic sulfides and/or organic polysulfides. A subsurface decrease in the humic acid C:S atomic ratio to 56 + or -2 suggests that the upper 4 cm of marsh sediment is the locus for humic sulfur formation. S. alterniflora detritus and microbial biomass cannot fully account for observed sulfur enrichment of humic C:S atomic ratios. The enrichment of humic substances by sulfur is probably via reaction of reduced sulfur compounds with organic matter. A humic sulfur formation rate of 10.6 mi-

cromoles S/cu cm/a is calculated for the surfa sediments and leads to an areal production of 18 micromoles S/sq cm/a of humic sulfur. Humic sulfur formation and preservation is enhanced by the limited availability of iron for the rapid precipi-tation of iron sulfide minerals and the apparent resistance of organic sulfur compounds towards reoxidation to sulfate, especially in the upper 9 cm of marsh sediment where inorganic sulfur compounds are rapidly oxidized. rocks, Tidal flats.

Microbial mats are ancient biological phenomena which have been documented in fossil records as laminated sedimentary rocks of domal, columnal, minimated sedimentary rocks of domal, columnal, or other geometrical structures collectively termed stromatolites. The macroscopic and microscopic characteristics of mats and their annual growth were studied in microbial communities of stratified phototrophic bacteria in laminated intertical sediments could be seen to ments north of Estuary El Punte, near San Carlos, Baja California Sur, Mexico. The mats were locat-Baja California Sur, Mexico. The mats were location and along meandering mangrove-lined tidal channels. Their thickness ranged from 0.5 to 25 cm. Square-meter areas of polygonal mats were found in several ponds infiltrated by sea water. The principal microbial community of the upper surface of the various microbial mat morphotypes was identified as cyanobacteria of the general Micrococleus, Lyngbya, Phormidium, and Oscillatoria. Other less prominent cyanobacteria were Pseudan. crocious, Lyngoya, Phormidium, and Oscillatoria.
Other less prominent cyanobacteria were Pseudanabaena, Spirulina, Synechococcus, and Gloeocapsa. There were also many unidentified diatoms at lower densities. The second inward reddish layers of microbial mats contained similar cyanobacterial genera plus anoxygenic phototrophic bac-teria identified as Chloroflexus, Thiocapsa, Chromatium, Prosthecochloris, Rhodopseudomonas, and Chlorobium and several unidentified bacteria. and chorosoum and several undentured outcern.

In-situ measurements on the growth of the mats, from intermittent tide sites, showed an annual buildup of two layers: green and reddish. These layers correspond to a vertical growth of 1.4 plus or minus 0.27 mm/yr. Permanently submerged or mmus U.21 mm/yr. Permanently submerged mats did not show vertical growth during the same observation period. Information obtained from these mats may be useful in the climatic reconstruction of Baja California Sur and to elucidate the forms of preserved fossil stromatolites. (Medina-PTT) W91-11400

lates, Food chains, Food habits, Growth rates, Physical properties, Protozoa, Salinity, Seasonal variation, Water temperature.

At least 16 species of the rotifer Synchaeta were found in the coustal waters between Hiddensee Island and the Darss-Zingst peninsula (Germany). Species of Synchaeta are able to ingest particles ranging in size from bacteria to rotifers, including Cyanophyta, algae, flagellates, and ciliates. Species such as S. fittoralis, S. oblongata, and S. lakowitziana prefer cooler waters (<15 C), while S. cecilia, S. t. kitina, and S. triophthalma are found in warmer waters (>15 C); S. vorax seems to be euthermal. Some of the marine Synchaeta species were found at salinities down to 3 ppt, while some tolerated salinities up to 5 ppt. Analysis of field data revealed growth r-values for S. cecilia (Sept./Oct. 1983, 14 C) and S. vorax (Feb./Mar. 1984, 2-3 C) of 0.11 and 0.01/d, respectively. Routine sampling revealed that the highest abundance of Synchaeta spp. occurred in early spring and autumn. In early spring, Synchaeta account for most of the metazooplankton biomass (>60%) and are able to consume a significant fraction of the spring peak of phytozooplankton and protozooplankton production. Their use as a food source by higher trophic levels seems to be of minor importance. (Doria-PTT)

Environmental Biology of Fishes EBFID3, Vol. 31, No. 2, p 109-121, June 1991. 2 fig. 9 tab, 24 ref. Halifax Department of Fisheries and Oceans Contract No. 05080-00257.

Descriptors: \*Intertidal areas, \*Nova Scotia, \*Fish populations, Biological studies, Ecosystems, Seaweed, Cunner, Sculpin.

In Nova Scotia the annual harvest of the intertidal seaweed Ascophyllum nodosum exceeds 20,000 tons. This study investigated the possible impact of removal of the seaweed on intertidal abundance of fish in small areas and their gut contents. At sites near Lower Argyle, Nova Scotia, absolute abundance of fish in small areas with Ascophyllum removed and intact was determined with pop-up seines. Gut contents were investigated from fish collected with the seines and with trammel nets. Number and weight of fish were not significantly different between cleared and intact areas and averaged 4.6 individuals and 160 g/400 sq m during June to October. Cunner and sculpins had more food in their guts when leaving then when entering the intertidal, but only cunner had more food in their stus when leaving intact ares than when leading cleared areas. Most fish captured in the intertidal were small (< 15 cm) and of no commercial value, and the numbers of commercial species were too low to be of much value. Numbers of fish in the intertidal was significantly lower than in the shallow subtidal. This study provided no evidence for adverse effects of the removal of patches of Ascophyllum on fishes. RESEARCH ON CLOUDS AND PRECIPITA-TION: PAST, PRESENT AND FUTURE, PART

Washington Univ., Seattle. Dept. of Atmospheric Sciences.

Bulletin of the American Meteorological Society BAMIAT, Vol. 72, No. 2, p 184-191, February 1991. 6 fig, 1 ref.

Descriptors: \*Acid rain, \*Climatic changes, \*Cloud seeding, \*Clouds, \*Global warming, \*Meteorology, \*Precipitation, Chemistry of precipitation, Cloud physics, Research, Weather.

Starting in the 1940s, an important spin-off from cloud physics research attempted to modify clouds and precipitation by artificial seeding. During the 1950s-1970s, many viewed clouds as something that could be readily milked to produce precipitation. The history of cloud seeding provides a subtory lesson on the need for sound basic research to precede attempts to operations. In the early 1980s, the importance of chemical reactions in clouds to acid deposition became more widely recognized, making cloud chemistry a discipline in its own right. Currently, thought turns increasingly to global change. Land, ocean, and clouds are seen as important players in global change, with the feedback effects of clouds being one of the major areas of uncertainty. Clouds are destined to remain near center stage in meteorological research. Their study will uncreasingly involve scientists with multifarious interests and backgrounds. Although large multidisciplinary programs will provide new opportunities to tackle some important problems, this approach is not necessarily the best way to tackle all of the outstanding problems in cloud research. Eight species of Sonoran Desert riparian trees and shrubs were examined in a greenhouse-based study of salinity tolerance at six levels: 0, 1,500, 6,000; 18,000; 36,000; and 60,000 mg/L. Analysis of percent survival and morphological growth response indicated that two of the eight species, Populus fremontii and Salix gooddingii exhibited no tolerance above 1,500 mg/L. Tessaria sericea was intolerant of salinity levels of 18,000 mg/L and above. Atriplex lentiformis and Tamarix chinensis exhibit-

ed significant growth decreases at 36,000 and 60,000 mg/L. Prosopis juliflora var. torreyana, and P. pubescens growth responses were not readily detectable because growth under experimental conditions was slow. Indications of salt tolerance were observed in Allenrolfea occidentalis growth response, and the data suggested greater growth response at intermediate salinity levels. Laboratory measurement of spectral reflectance of leaves suggested that salt stress was discernable through examination of the location of the 'red edge' of the electromagnetic spectrum, and that measurement of reflectance may provide a predictor or indicator of salinity stress. Measurement of photosynthesis show that salinity clearly reduces the rate of carbon gain in all studied species. Technical problems will have to be overcome before measurement of photosynthesis will be a useful tool for detecting salinity damage in the field. Measurements of chlorophyll fluorescence indicate that under field conditions differences in this parameter are unlikely to appear in relation to salinity stress. (Author's abstract) W91-10752

Agricultural Water Management AWMADF, Vol. 19, No. 1, p 51-66, January 1991. 5 fig, 7 tab, 18 ref.

Descriptors: \*California, \*Crop yield, \*Drainage water, \*Irrigation water, \*Lysimeters, \*Saline soils, \*Salinity, Decision making, Imperial Valley, Saline water, San Joaquin Valley.

Lysimeter data were used to estimate relationships between yield, water quantity and quality, soil salinity and drainage volumes for a variety of conditions similar to those prevailing in the San Joaquin and the Imperial Valleys of California. Coefficients for the various estimated functions were found to be statistically significant and in most cases were also in agreement with findings provided by previous studies. A major conclusion was that a direct relation between yield and average seasonal soil salinity does not apply to conditions where several limiting factors are interrelated. The results imply that the lysimeter-based functions can also be used to develop information needed for decision making. Lysimeter experiments are relatively easy to control and can be used to simulate a variety of environmental conditions. The lysimeter results can verify normative predictions of the models, and if necessary to calibrate for local conditions. Relationships for crops can be used to evaluate different alternatives of irrigation/drainage management on a field or farm level. (Author's abstract)

RESIDENTIAL WATER CONSERVATION:

Arizona Univ., Tucson. Office of Arid Lands Stud-

M. M. Karpiscak, K. E. Foster, and N. Schmidt. Water Resources Bulletin WARBAQ, Vol. 26, No. 6, p 939-948, December 1990. 8 fig, 2 tab, 16 ref.

Descriptors: \*Demonstration projects, \*Domestic water, \*Water conservation, \*Water reuse, \*Water schortage, \*Water use, Arid lands, Arizona, Evaporative cooler water use, Graywater reuse, Residential water conservation, Water costs, Water demand, Water harvesting, Water management, Water resources

The issue of water conservation has received the most attention in areas where the prospect of water shortages is most imminent. Arid areas with finite groundwater supplies and scarce surface water re-sources, such as the American Southwest, face sources, such as the American Southwest, face water supply problems now that will affect other areas later. In 1985, the University of Arizona designed and retrofitted Casa del Agua (CDA), a residential water conservation experimental and demonstration home in Tucson, Arizona. The single-family residence was retrofitted with water-conserving fixtures, rainwater harvesting, and graywater reuse systems. Detailed measurements of water use during the subsequent four years provide a useful database for evaluating the potential benefits of residential conservation techniques tial benefits of residential conservation techniques and technologies on overall water use. The results and technologies on overall water use. The results of the study revealed that the demand for domestic water was reduced significantly at the house without reducing the residents' quality of life. The use of municipal water was reduced by 66 percent to 148 gallons per day (gpd) and total household use was reduced by 27 percent to 245 gpd. Graywater reuse averaged approximately 77 gpd or 32 percent of the total household water use. Evaporative cooling required about 15 gpd. Water use for toilet flushing was only 9 gallons per capita per day (gpcd) or 14 percent of interior water use. Water savings not only help alleviate the demand for a or 14 percent of interior water use. Water savings not only help alleviate the demand for a diminishing resource, but also reduce both water and energy bills for households. (Korn-PTT)

WATER CONTROL SYSTEMS AND THE TRA-DITIONAL FESTIVAL AT MIYAWAKI, ON THE SETO INLAND SEA.

National Inst. of Multimedia Education, Chiba

(rapan). T. Oohashi, and M. Kono. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 653-657, 1991. 7 fig, 4 ref.

Descriptors: \*Irrigation practices, \*Japan, \*Public participation, \*Seto Inland Sea, \*Water demand, \*Water resources management, Agriculture, Climates, Coastal areas

In Miyawaki, Japan, a village facing an enclosed coastal sea, little rain falls, due to the typical Seto coastal sea, little rain falls, due to the typical Seto Inland Sea climate. Therefore, the control of irrigation system facilities, indispensable for paddy field cultivation, has been a constant concern of the village. The basic social unit for water control and management is made up of small neighborhood units. Larger groups are formed by a number of these small units located close together and utilizing the same waterway. The close social structure that is enhanced by local festivals is an important aspect of water management strategies. A type of negative feedback-control occurs in the community when conflict arises concerning the irrigation negative teedoack-control occurs in the communi-ty when conflict arises concerning the irrigation system. Rather than risk disrupting the social struc-ture surrounding the festival, compromises are made in regard to water use. The traditional wisdom inherited in Miyawaki has been adapted to

solve problems encountered in modern society. (Brunone-PTT) W91-10591

MODEL OF AMMONIA VOLATILIZATION FROM APPLIED UREA. V. THE EFFECTS OF STEADY-STATE DRAINAGE AND EVAPORA-

Oxford Univ. (England). Soil Science Lab. G. J. D. Kirk, and P. H. Nye. Journal of Soil Science JSSCAH, Vol. 42, No. 1, p 103-113, March 1991. 5 fig, 1 tab, 17 ref.

Descriptors: \*Ammonia, \*Drainage effects, \*Evaporation, \*Fertilization, \*Model studies, \*Ureas, \*Volatilization, Alkalinity, Boundary conditions, Continuity equation, Dispersion, Drainage, Hydraulic properties, Irrigation, Mathematical studies, Rainfall, Soil water, Solute transport, Water

The effectiveness of urea, which is now the major nitrogen fertilizer in both temperate and tropical nitrogen retuizer in both temperate and tropical agriculture, is in many cases, severely limited by losses through ammonia volatilization. A mechanistic model has been developed that enables the prediction of ammonia volatilization and the distribution in soil of urea, ammoniacal nitrogen, and pH, following urea application. The model has been expanded to account for the effects of steadystate water movement by drainage or evaporation when the soil does not dry out to any great extent. The model was used to asses the effects on volatiliation of evaporating conditions and of irrigation or rainfall. Preliminary modeling results revealed how upward movement of water during evaporation increased velocities. now upward movement of water during evapora-tion increased volatilization by carrying urea-de-rived NH4(+) and HCO3(-) ions upward, thereby increasing the concentration of ammonia gas at the surface. Conversely, water drainage reduced vola-tilization by carrying the dissolved solutes into the soil. (Korn-PTT) (See also W91-10806)

MODEL OF AMMONIA VOLATILIZATION FROM APPLIED UREA. VI. THE EFFECTS OF TRANSIENT-STATE WATER EVAPORATION.

Oxford Univ. (England). Soil Science Lab. G. J. D. Kirk, and P. H. Nye. Journal of Soil Science JSSCAH, Vol. 42, No. 1, p 115-125, March 1991. 6 fig, 3 tab, 16 ref.

Descriptors: \*Ammonia, \*Evaporation, \*Fertilizers, \*Model studies, \*Ureas, \*Volatilization, Boundary conditions, Continuity equation, Convection, Diffusion, Finite difference methods, Hydraulic properties, Hydrogen ion concentration, Mathematical studies, Moisture profiles, Neutralization, Soil water, Solute transport, Temperature

A mechanistic model that predicts ammonia volatilization and the distribution in soil of urea has been expanded to account for the effects of tranbeen expanded to account for the effects of transient-state water evaporation when the soil surface dries significantly. Solute and water continuity equations were derived and solved using the finite difference method. For the wide range of soil hydraulic properties considered in the investigation, the effects of a dry soil layer on the rate of volatilization supplemented the effects of increased convective supply of NH4(+) and HCO3(-) ions to the soil surface. The dry layer resulted in increased gaseous NH3 diffusion through the soil, and thereby increased the flux of NH3 across the soil surface and the neutralization of H(+) ions generated by volatilization. ADOPTION OF WATER-SAVINGS PRACTICES BY IRRIGATORS IN THE HIGH PLAINS. Kansas State Univ., Manhattan. Dept. of Geogra-

D. E. Kromm, and S. E. White. Water Resources Bulletin WARBAQ, Vol. 26, No. 6, p 999-1012, December 1990. 2 fig, 8 tab, 19 ref.

Descriptors: \*Agricultural water, \*Great Plains, \*Groundwater depletion, \*Irrigation, \*Irrigation

practices, \*Water conservation, Energy costs, High Plains, Irrigation efficiency, Legislation, Sur-veys, Water policy.

The High Plains has been viewed as an immense and regarden because of its highly productive agricultural system based on irrigation. Irrigated agricultural system based on irrigation. Irrigated agriculture in the High Plains aquifer region peaked about 1980, when over 17.8 million acre feet of water were pumped to irrigate approximately 14 million acres of farmland. Rising energy costs and ground-water depletion resulted in a 20 percent decline in irrigated acreage harvested between 1978 and 1987. There is a growing concern that the region may be returning to its natural state of a vast shortgrass prairie. Efforts to avoid this scenario and to ensure continued survival of the integrated and to ensure communes survival or the integrated agribusiness economy focus on conserving water in irrigation. A survey of 709 irrigators was conducted in ten counties in Kansas, Nebraska, Oklahoma, and Texas to provide information about the frequency with which irrigators adopted each of 39 water-saving practices and the variation of adopwater-saving practices and the variance was found primarily to be a function of location and secondarily to be influenced by the number of wells, the type of irrigation system, depth to water, age, and educairrigation system, depth to water, age, and educa-tion. Locational differences remained strong even tion. Locational differences remained arroing even when the influence of secondary factors were controlled. The future of irrigated agriculture in the High Plains will undoubtedly be influenced by crop prices, energy costs, state legislative sponses, changes in national farm policy, and the extent of past groundwater depletion. However, extent of past groundwater depletion. However, irrigators can help their situation if they select the most cost effective mix of water-saving practices.

ECONOMIC ASSESSMENT OF THE WATER QUALITY BENEFITS OF CONSERVATION TILLAGE ON SOUTHWESTERN ONTARIO CROPLAND.

Guelph Univ. (Ontario). Dept. of Agricultural Ecics and Bu

G. Fox, and E. J. Dickson. IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 485-493, 3 tab. 31 ref.

Descriptors: \*Agricultural water, \*Conservation, \*Conservation tillage, \*Cost-benefit analysis, \*Nonpoint pollution sources, \*Ontario, \*Water pollution control, \*Water quality, Costs, Economic aspects, Sediment control

Non-inversion primary tillage in cash crop production has been promoted as a soil and energy conserving production system for two decades. More recently, it has been linked to improvements in surface water quality, through the reduction of the rate at which sediment is displaced from cropland.

#### Field 3—WATER SUPPLY AUGMENTATION AND CONSERVATION

#### **Group 3F—Conservation In Agriculture**

Four different forms of row crop tillage were analyzed to estimate the effects of conservation tillage on water quality. The Soil Conservation teconomics (SOILEC) model was used to estimate the on-farm impacts of alternative management practices. The Guelph model for evaluating the effects of Agricultural Management systems on Erosion and Sedimentation (GAMES) was used to estimate changes in sediment delivery to streams and lakes resulting from changes in cropland management practices. With one exception, off-farm benefits are larger than on-farm costs. The on-farm const, however, are borne by the farm operator, whereas the off-farm benefits accrue to diverse stakeholders downstream. This is a classic example of an economic externality. Farmers have little incentive to adopt the socially efficient production system since they are not held accountable for the external costs imposed on others. Local matters play a role in the evaluation of costs and benefits of soil conservation. While the adoption of conservation tillage generates improvements in water quality whose value exceeds the costs imposed on farms, this strategy may not be the most cost-effective approach to sediment control. Investments in stream bank rehabilitation, various sedi-ment trapping devices located along waterways, and a reduction of intensity of cultivation near streams and rivers, may generate comparable total benefits at a substantially lower cost than wide-spread use of conservation tillage. MICRO-TARGETING CROPLAND RETIRE-MENT FOR WATER QUALITY IMPROVE-MENT: MEASURING THE BENEFITS OF IN-CREASED INFORMATION.

nesota Univ., St. Paul. Dept. of Agricultural and Applied Economics

K. Kozloff, and S. J. Taff. IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 507-514, 1 fig,

Descriptors: \*Agriculture, \*Cost-benefit analysis, \*Land use, \*Nonpoint source pollution, \*Water pollution control, Economic aspects, Soil conser-

The relative cost-effectiveness of micro-targeting cropland retirement programs for reducing nonpoint source pollution is examined using a con er model to simulate the effects of various program options in a study watershed with respect to budget outlays for annual rental payments, reduc-tion in downstream sediment and nutrients, and reduction in on-site erosion. Options that incorporated information about heterogeneous economic and physical characteristics across land parcels were more cost-effective than those that did not. The marginal cost-effectiveness of all schemes decreased as the proportion of land retired increased within the watershed. (See also W91-11003) (Author's abstract) W91-11052

NATIONAL PROGRAM FOR SOIL AND WATER CONSERVATION, ITS EFFECT ON USDA SERVICES.

R. M. Gray, and J. A. Maetzold. IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Man-agement. Freshwater Foundation, Navarre, Minne-

sota. 1989. p 115-124.

Descriptors: \*Agricultural practices, \*Environmental policy, \*Erosion control, \*Management planning, \*Nonpoint pollution sources, \*Watershed management, Agricultural chemicals, Erosion, Groundwater quality, Legislation, Regulations Soil conservations tions, Soil conservation.

The National Conservation Program (NCP) of the US Department of Agriculture (USDA) was developed as part of The Soil and Water Conservation Act of 1977. In the 1982 NCP, USDA analyzed eight resource areas of concern and identilight resource areas of concern and identified three-erosion, upstream flooding, and water conservation—as having the highest priority. As a result of the 1982 NCP, USDA redirected its activities to: focus assistance more sharply on the most critical resource areas; strengthen the particular interests in the contraction of the contrac nership of Federal, State, and local agencies and private organizations; and, improve management of existing conservation programs. For the 1988-97 period, USDA has modified its priorities, and is directing its activities to address the top priorities, which are: (1) reduce the damage caused by exceswhich are: (1) reduce the damage caused by excessive soil erosion on rural lands. In support of erosion control, the Food Security Act of 1985 authorized the establishment of vegetative cover on about 10% (45 million acres) of cropland. Meanwhile, the Highly Erodible Lands Provision will require that farmers who 'sodbust' highly erodible land must have a conservation system in place in order be able to participate in USDA programs; and (2) to protect the quality of surface and groundwater against harmful contamination from agricultural nonpoint sources and thereby maintain the quality of water available for beneficial use. The USDA plans to work with the states and local computative in developing and implecial use. The USDA plans to work with the states and local communities in developing and implementing agrichemical risk management methods. The USDA will also support research activities in these areas as well as administer the ongoing programs that encourage agricultural operators to protect water quality. FARMER-INITIATED PROJECT TO PRO-MOTE SUSTAINABLE AGRICULTURE IN CO-OPERATION WITH THE EXTENSION SERV-

ICE.

D. E. Exner, and R. L. Thompson.

IN: Agrichemicals and Groundwater Protection:
Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 401-406.

Descriptors: \*Agriculture, \*Information exchange, \*Information transfer, \*Iowa, \*Nonpoint pollution sources, \*Organizations, Farming, Research.

At the Biofarming Workshop held in 1985, a suggestion was made to establish a farmers' organization that would share knowledge gained from farming experience. This organization came to be known as the Practical Farmers of Iowa (PFI). From its inception, PFI has worked to improve the farmer-researcher dialogue by taking the position that both farmers and researchers have an important role to play in the development of sustain agriculture. A source of contention has been that farmers and researchers have not shared a common frame of reference. There is a need for on-farm trials that are convincing to both farmers and scientists and that are simple enough and 'farmable' enough to be carried out completely by farmers. The design used by PFI is the paired-comparison, with at least six pairs of narrow, side-by-side test strips running all the way across the field. PFI has approached both foundations and state agencies for support to extend its on-farm demonstration program. A cooperative arrangement now exists between PFI and the Extension Service. This artween PFI and the Extension Service. Inis arrangement is intended to present sustainable agriculture alternatives to every farmer in the state. PFI will gain access to Extension's well-developed communication network and to the program development skills of its professionals. The Cooperative Extension Service will increase its knowledge base regarding sustainable agriculture, which will improve information delivery both to the farmers and to its own personnel. TRICKLE IRRIGATION OF SUNFLOWER WITH MUNICIPAL WASTEWATER.
Agricultural Research Inst., Nicosia (Cyprus).

L. Papadopoulos, and Y. Stylianou. Agricultural Water Management AWMADF, Vol. 19, No. 1, p 67-75, January 1991. 6 tab, 17 ref.

Descriptors: \*Crop yield, \*Fertilizers, \*Nutrient requirements, \*Sunflowers, \*Trickle irrigation, \*Wastewater utilization, Effluents, Municipal wastewater, Nitrogen, Nutrient concentrations, Phosphorus, Plant growth, Potassium, Salinity.

A field experiment was conducted for three years on a Calcaric Lithosol to study the influence of treated municipal wastewater in comparison with freshwater, supplemented with four N or P levels, on soil fertility and on growth and yield of trickle-irrigated sunflower (Helianthus annus L). The N irrigated sunflower (Helianthus annus L). The N concentrations in irrigation water were nil, 30, 60, or 90 mg/L. An efficient use of N, with no residual NO(3)-N in soil, occurred with the additional 30 and 60 mg N/L in wastewater and freshwater, respectively. The maximum seed yield obtained was significantly greater in the effluent-irrigated was significantly greater in the effluent-irrigated with significantly greater in the yield was obtained with the 60 mg N/L(-i). The P levels were nil, 15, 30, or 45 mg/L. With the effluent no supplementary P was needed for high yield of good quality. With treated wastewater less N and no P fertilizers are needed by sunflower for high yield of good quality. (Author's abstract)

WATER USE OF A WINTER WHEAT CULTI-VAR (TRITICUM AESTIVUM).

Akademia Rolnicza, Poznan (Poland). Dept. of Vegetable Crops. T. Islam.

Agricultural Water Management AWMADF, Vol. 19, No. 1, p 77-84, January 1991. 2 fig, 4 tab, 6 ref.

Descriptors: \*Crops, \*Evapotranspiration, \*Irrigation, \*Irrigation requirements, \*Water use, \*Wheat, Bulgaria, Consumptive use, Field capacity, Plant growth, Root zone, Soil moisture.

A field trial with a winter wheat cultivar (triticum aestivum) was conducted at the experimental field of the Introduction and Plant Resources Institute Sadovo, Bulgaria, during 1982-83 and 1983-84. Three treatments, two irrigated and one non-irrigated, were used to determine the water use of winter wheat at the central-eastern region of Bulgaria. Irrigation was given to maintain two soil moisture regimes of 65-70-65% and 75-85-75% of moisture regimes of 65-70-65% and 75-87-75% of field capacity during the periods emergence to jointing, jointing to flowering and flowering to dough stage, respectively. To maintain both the regimes irrigations were required in both the experimental years, but in different growth stages. Among the treatments the non-irrigated one showed the lowest peak evapotranspiration of 3.7 mm/day and the treatment irrigated at 75.88-75% showed the lowest peak evapotranspiration of 3.7 mm/day and the treatment irrigated at 75-85-75% of field capacity showed the highest peak of 5.8 mm/day. The total water use under non-irrigated condition and irrigated at 75-85-75% of field capacity was 335 mm and 482 mm, respectively. Three irrigations during the post-winter period were required to maintain the latter moisture level, which used the highest amount of water among all

REPORT OF THE RIVER MASTER OF THE DELAWARE RIVER, FOR THE PERIOD DE-CEMBER 1, 1988-NOVEMBER 30, 1989.

Geological Survey, Reston, VA. S. P. Sauer, W. E. Harkness, B. E. Krejmas, and K. E. White.

A. E. Wille.

Available from the US Geological Survey, Books and Open-File Reports Section, Box 25425, Federal Center, Denver, Co 80225-0425, Open-File Report 90-551, 1990. 89p, 7 fig, 22 tab.

Descriptors: \*Delaware River Basin, \*Legislation, \*Water management, \*Water resources management, \*Water supply, Delaware River, Drought, Flow rates, New Jersey, New York, New York City, Precipitation, Regulations, Runoff, Water

A Decree of the Supreme Court of the United States in 1954 established the position of Delaware River Master. The Decree authorized diversions of River Master. The Decree authorized diversions of water from the Delaware River basin which require compensating releases from certain New York City owned reservoirs to be made under the supervision and direction of the River Master. Reports to the Court, not less frequently than annually, were stipulated. During the 1989 report year, December 1, 1988, to November 30, 1989, precipitation and runoff ranged from below average to above average in the Delaware River basin; for the year as a whole, precipitation was 1.45 inches above average. Reservoir storage in the basin declined into the drought-warning zone of the operation curves for the reservoirs on January 11, 1989 and operations were conducted as prescribed in the Interstate Water Management Recommendations of the Parties to the Decree from January 16 to February 8. From February 9 to April 30 at the request of the Parties to the Decree releases to meet the Montague flow objective were suspended as part of an operation designed to suspended as part of an operation designed to avoid or delay entry into a drought emergency in avoid or delay entry into a drought emergency in the basin. In response to increased precipitation in April and May, storage increased and operations were returned to those prescribed in the Decree on May 12. Storage improved from a low of 45.2% of capacity on February 15, to 99.7% of capacity on June 25, and remained above the median for the remainder of the report year. Diversions from the Delaware River basin by New York City and New Jersey did not exceed those authorized by the terms of the Amended Decree. Releases were

made as directed by the River Master to relieve thermal stress in the streams downstream from the reservoirs at other times. The excess release quantity as defined by the Decree was expended on October 18, 1989 and the Montague design rate was reduced from 1,850 cu ft/s to 1,750 cu ft/s. New York City and New Jersey complied fully with the terms of the Decree and with the directives of the River Master during the year. (Author's abstract) thor's abstract) W91-10765

Descriptors: \*Aquatic weed control, \*Herbicides, \*Phenoxy acid herbicides, \*Riparian vegetation, Biomass, Spraying.

The non-persistent herbicides glyphosate and 2,4-The non-persistent herbicides glyphosate and 2,4-D amine were applied to riparian stands of R. japonica on the banks of the River Cynon, South Wales at doses of 2154 g and 2790 g active ingredient/ha respectively, using different spraying regimes. Glyphosate was tested with one or two applications per season, 2,4-D amine with two only. Two weeks after spraying, the biomass and leaf area ratio of shoots in all treated plots was depressed but was significantly lower (P<0.01) in the 2,4-D amine plots. Ten weeks after treatment, shoots began to recover but the biomass was still < 40 % of the control areas. Rapid recovery (six weeks after treatment) of Leaf Area Ratio was also observed. Second applications of glyphosate and observed. Second applications of glyphosate and 2,4-D amine to the respective plots resulted in shoot death after four weeks. Two applications of

2,4-D amine are recommended, one early in the season to reduce vigor and height of R. japonica (which precludes the use of spraying booms and increases the application efficiency) and a second in mid-season to achieve control. Successful control of R. japonica after herbicide treatment is dependent on continued management (further spraying) of treated areas to suppress possible regrowth during the following season. Descriptors: \*Canada, \*Flood basins, \*Flood fore-casting, \*Hungary, \*International waters, Danube River, Drava River, Floods, Ipoly River, Koros River, Mountain watersheds, Political aspects, Tisza River

For a country situated downstream of another on a watershed, all hydrological forecasts on upstream watersheet, an introduction of the state of the transboundary rivers have to be obtained from its upstream neighbor. It also puts the downstream country at the mercy of the upstream one, being subject to the results of it incidentally polluting the subject to the results of it incidentally polluting the control structures. Hungary, as a small country having a great number of water courses with frequent flooding problems, faces this problem with all but one of its rivers. All the rivers but the Zagyva originate in the mountainous areas across its borders bringing, more often than not, flash flood events to the Hungarian plain. In this setup, sudden floods can come down the rivers without any advance notice if the information from the neighbors happens to come down the rivers without any advance notice if the information from the neighbors happens to be late. Every neighbor acts differently in this matter. Therefore, the reliability of forecasts depends not only on the hydrological travel time but also on the travel time of information. The latter is a combination of natural and political phenomena. The varying situations on the Danube, Tisza, Koros, Ipoly and Drava Rivers are discussed. The situation in Canada is different because of the different political background However, informasituation in Canada is different because of the different political background. However, information travel may well be blocked here too, by potential bad communication between provinces or even Conservation Authorities. (See also W91-11003) (Author's abstract) W91-11015

Descriptors: \*Economic aspects, \*Environmental impact, \*Legal aspects, \*Political aspects, \*Social aspects, \*Water management, \*Water resources management, Institutional constraints, Public health, Resources management, Water policy, Water quality management.

A variety of essays, contained in this collection, recognize that water management is multi-dimen-sional, embracing technical, political, social, legal, environmental, and economic elements. Effective management of water resources often depends more on the ability to maneuver within institutionmore on the ability to maneuver within institution-al constraints than to design technologic fixes; it is suggested that there is a need for institutional reform. The six essays specifically address the past, present, and future of water resources manage-ment; the federal role in the solution of future management problems; water and human health; and the dynamics of water policy. The history of water resources management in the U.S. antedates the Constitution. Water was naturally and abundantly available in the 13 original states. Water resources management at the end of the 18th century consisted of development of springs and wells for drinking and stock water, construction of canals, channel improvements and locks to facilitate water transportation. Flourishing railroads resulted in few improvements for naviga-tion. In the 1870's, however, flooding on the lower Mississippi River and provision for water supplies for irrigation of arid lands in western states were recognized as problems. It was not until 1879 that Congress authorized the creation of the Mississippi River Commission to undertake the improvement of the Mississippi River. The economic depression of the 1930's heralded the creation of the Water Resources Committee of the National Resources Commission, that later metamorphosed into the National Resources Planning Board. Water management plans were initiated for most of the river basins of the U.S. Public sentiment in favor of water pollution control led to authorization of water quality control investigations in the 1950's. The National Water Commission was created in 1968, but offered solutions too drastic for Congressonal approval. Finally, federal responsibility in-creased with the enactment of the 1972 Water Pollution Control Act. The Reagan era ushered in decreased Federal expenditures on nonmilitary programs and returned many responsibilities to the states. Water pollution control legislation in 1988 states. Water poliution control legislation in 1938 turned that attitude around slightly by establishing Federal grants for construction of publicly-owned treatment plants and other facilities for water pollution control. As water resources problems continue to evolve, the Federal government will have to become more involved. Trends suggest that there will be much greater reliance on groundwater. Declining water availability and water quality will force user restrictions. (See also W91-11206) (Mertz-PTT)

#### FUTURE DIRECTIONS FOR WATER RE-SOURCES.

New Jersey Dept. of Environmental Protection, Trenton. Div. of Water Resources. W. Whipple. IN: A 25th Anniversary Collection of Essays by

Eminent Members of the American Water Resources Association. AWRA Special Publication No. 89-2. American Water Resources Association, Bethesda, Maryland. 1989. p 9-13.

Descriptors: \*Clean Water Act, \*Flood control, \*Future planning, \*Hydroelectric power, \*Water resources, \*Water resources management, Environmental effects, Irrigation, Storm water management, Waste disposal, Water conservation, Water law, Water pollution control, Water resources development, Water supply.

The great era of water resources got well underway with the passage of the Flood Control Act of 1936. For the next 30 years large Federal programs featured flood control, navigation, hydroelectric power, and irrigation. The environmental movement of the 1960's and the Clean Water Act of 1972, created a basic shift in national priorities. As the nation urbanized, environmental pressures became more acute. Water resources development started involving community life. In addition, waste control and disposal programs became ranking activities in the environmental field, encompassing air, land and water environments. As fossil fuels become scarcer in the future, the value of hydroelectric power will increase. Few new projects will be built, however, because the best projects will be built, however, because the best sites remaining cannot be used without unacceptable economic, environmental and social dislocation. Navigation improvements will be maintained and some channels deepened; but few new systems will be built. The planners of flood control will find it ever more difficult to find acceptable new reservoir sites. Further general increases in flood damages appear inevitable, especially along the smaller rivers and streams. Growth in flood damages due to new development can be precluded on a control with the control of the contr ages due to new development can be precluded on small streams, and minimized on larger streams, by programs of stormwater management. As water shortages due to drought become more serious, water conservation will increase in popularity and water conservation will increase in popularity and practicality. By far the greatest change comes with the increasing importance of pollution control. A major technological change in the treatment of water for potable uses will be made when the EPA finally publishes new standards for trihalomethanes. Regional water management plans will be increasingly applied. Urbanization ups the pressures for better planning and more effective environmental protection. Despite our best efforts, a new generation of planners and analysts will have new generation of planners and analysts will have their hands full. (See also W91-11206) (Mertz-PTT) W91-11208

# PAST, PRESENT, AND FUTURE OF WATER USE AND MANAGEMENT.

Academy of Natural Sciences of Philadelphia, PA. R. Patrick

R. Patrick.
III: A 25th Anniversary Collection of Essays by Eminent Members of the American Water Resources Association. AWRA Special Publication No. 89-2. American Water Resources Association, Bethesda, Maryland. 1989. p 15-19.

Descriptors: \*Future planning, \*History, \*Stream pollution, \*Water management, \*Water pollution control, \*Water resources management, \*Water use, Acid mine drainage, Aquifers, Biological oxygen demand, Surface-groundwater relations, Toxicology, Water conservation, Wetlands.

Between 1930 and 1940, waterways were at a low ebb. Pollution was rampant through many of the most important riverine systems. During the 1940's and 1950's, the first real concerns by citizens were surfacing concerning water quality. The first laws implemented focused on reductions of biological oxygen demand and acid mine wastes. At this time, the way to measure the toxicity of a waste to aquatic life was by the 96-hour toxic level median, and sometimes only a 24-hour toxic level median, and sometimes only a 24-hour toxic level median. was used. In 1968 a methodology using three steps in the food web (primary producer, herbivore/ detrivore, and ominivore) was developed. Only recently has that method been put to use. Management of water resources was at a primitive state in the 1960's. Measures were often taken to solve the immediate needs of the user, rather than taking a long-term approach to the problems. Because water was free or very inexpensive, it was often cheaper not to fix a leak. Groundwater was really not known by the general public except as a source of well and spring water. The general philosophy was that it was free and available for the use of all in unlimited quantities. Few appreciated the imporin unlimited quantities. Few appreciated the impor-tance of wetlands as conservation areas for water, nor did they appreciate the fact that shallow aquifers and wetlands were often connected. Today, it is known that air, water, and land all interact and that it is not a solution to remove a pollutant from one phase of the environment and put it in another. Although billions of dollars have been spent on pollution control, very little has been directed into monitoring the results. In the future, the attitude toward water resources and future, the attitude toward water resources and groundwater must change. More care should be given to the conservation of precipitation and off-stream storage that doesn't interfere with the natural flow of streams should be developed. Wetlands are very important regenerators of shallow aquifers and should be preserved. The only way to increase the water supply after groundwaters and surface water are exhausted is to desalinate seawater. At present, this is expensive and produces difficult-to-dispose-of wastes. (See also W91-11206) (Mertz-PTT)

# FUTURE WATER MANAGEMENT PROB-LEMS: THE FEDERAL ROLE IN THEIR SO-LUTION.

Colorado State Univ., Fort Collins.

H. P. Caulfield.

H. F. Caumen.
III: A 25th Anniversary Collection of Essays by Eminent Members of the American Water Resources Association. AWRA Special Publication No. 89-2. American Water Resources Association, Bethesda, Maryland. 1989. p 21-29. 8 ref.

Descriptors: \*Environmental protection, \*Federal jurisdiction, \*Future planning, \*Rehabilitation, \*Water management, \*Water resources management, Clean Water Act, Economic aspects, Greenhouse effect, Water conservation, Water resources, Water resources development.

Federal dominance in water resources development is dead, whereas dominance is increasing in the control and implementation of environmental protection. In the 21st Century water quality will continue to be a major water management problem. The sources of pollution are so great and the problems of control so intractable that these water management problems will continue indefinitely into the future. The Federal role is inescapable. Consumptive use versus instream flow will be a primary water management problem in the 21st Century. Ideological support for continued economic and population growth will be pitted, even more sharply than at present, against strong environmental beliefs on the need to retain and in some cases restore instream flows. Section 404 of the Clean Water Act of 1972 already gives the Federal Government the power to resolve such issues through the Army Corps of Engineers and ultimately the EPA. The greenhouse effect may be a national problem in the 21st Century, involving the location of agriculture, the flooding of coastal areas, the rise in the salt front in coastal rivers, and the development of new sources of municipal and Consumptive use versus instream flow will be a areas, the rise in the sait front in coastal rivers, and the development of new sources of municipal and industrial water. A large Federal outlay will be necessary to achieve timely solutions to water management problems. In this connection the Federal Government will have the option to provide funds for necessary rehabilitation of existing Federal water management revisities or to abandon them. al water management projects or to abandon them. The major water management problems of the U.S. will also be worldwide problems. (See also W91-11206) (Mertz-PTT) W91-11210

Water resources projects traditionally have been designed and operated with the objective of optimizing economic performance (i.e., maximizing net benefits, minimizing expected damages, etc.). More recently, the importance of additional performance in the design or operation of water resources sys-tems has been recognized. Reliability, resiliency, and vulnerability have been formulated as risk-based performance measures for the evaluation of a based performance measures for the evaluation of a real-time reservoir optimization model. The reser-voir operation model includes a multi-objective compromise programming algorithm to select, in real time, an optimal operating horizon for the reservoir. The utility of the risk-based performance criteria for comparing operational strategies result-ing from the selection of different parameters for the compromise programming algorithm is demon-strated. Although tradeoffs exist among the three strated. Attnough tradeous exist among the three performance evaluators, appropriate compromises can be reached among conflicting modeling goals. Any rational comparison of candidate operating strategies must consider the multi-dimensional character of the operational problem within the selection process. The work demonstrates that preferred operating strategies, in terms of risk-based performance criteria, can be selected in a systemat-ic manner. (Author's abstract) W91-11275

A distributed parameter, unit response formulation was developed for investigating strategies for managing groundwater use in an urban situation with aging groundwater use in an urban situation with competing water supply agencies considering economics, restrictions on drawdown, water rights and water quality maintenance. The model is deterministic and considers a single multi-year planning period. Water quality management issues are considered through aquifer flow control. Groundwater rights of individual water supply agencies are handled by accounting for groundwater flow across agency boundaries and by restricting well drawdowns. A response matrix formulation was used to develop a compact, nonlinear optimization model. Penalty Successive Linear Programming (PSLP) is used for model solutions. Example applications of the model to Salt Lake County, Utah are made for various demand scenarios such as uniform demand, demand growth and drought condimade for various demand scenarios such as uni-form demand, demand growth and drought condi-tions. The results from these applications show that economics, water quality and water rights consid-erations, as well as the spatial and temporal distri-bution of demand are important factors in deter-mining optimal groundwater development. The US Army Corps of Engineers, Vicksburg District, is investigating the feasibility of a project to supply surface water to agricultural water users to reduce the pumping stress on the Mississippi River alluvial aquifer in northwestern Mississippi. Three scenarios of groundwater withdrawal from the aquifer are evaluated using an existing ground-water flow model. The three scenarios represent: water flow model. The three scenarios represent:

(1) a projection of current trends of groundwater
pumpage; (2) groundwater pumpage that could be
expected with the proposed surface water diversion project supplying surface water to many of
the current groundwater users; and (3) groundwater
pumpage that could be expected with the surface water diversion project in operation and with
the remaining groundwater users following best
available technology water conservation practices.
Results for the first scenario indicate that the aquifer would be completely dewatered in some locations as early as 2007 and that, by 2030, the aquifer underlying an area of more than 800,000 acres of
the Delta (northwestern Mississippi) would be
completely dewatered. Results for the second scenario show a dramatic decrease in the rate of
decline of groundwater levels as compared to the nario show a dramatic decrease in the rate of decline of groundwater levels as compared to the first scenario. In 2030, under the second scenario, about three-fourths of the Delta would have a saturated aquifer thickness of > 100 ft. Water level declines from 1985 levels would be greatest in southern Sunflower and northeastern Washington Counties, and generally would be < 50 ft in these areas. The third scenario resulted in a substantial incremental decrease in the rate of decline of water levels Maximum declines from 1985 levels under levels. Maximum declines from 1985 levels under this scenario generally are < 30 ft, an increase of about 20 ft from the second scenario. Saturated thickness is increased by a similar amount. Historically, irrigation tanks served as important sources of groundwater recharge in the hard rock belt of India. Construction and maintenance of irrigation tanks were functionally linked with irrigation wells by groundwater recharge. Farmers voluntarily maintained the tanks because of an established tank maintenance system. Contemporary administrative and political changes have both promoted rapid exploitation of groundwater and discouraged maintenance of the tank systems that had sustained the groundwater resource leading to depletion. One corrective policy being considered depletion. One corrective policy being considered is the revitalization of tank systems for surface irrigation, groundwater management, and silt fertilization. Tank investments become more attractive when their groundwater and soil fertility effects are considered. Another policy is the removal of subsidies on electricity and credit for pump irrigation. A third is to establish groundwater districts to enforce a system of correlative rights through groundwater quotas in order to enable farmers to secure a predictable annual quantity of water. The Seto Inland Sea is one of the typical enclosed coastal seas of Japan. Kansai International Airport is under construction in Osaka Bay, 5 km off the coast of Senshu. The construction of seawalls in the airport island commenced in January 1987. the arport issued commenced in January 1887. With the opening of the airport scheduled for the spring of 1993, the construction of aboveground facilities will soon commence. The concentration of COD in drainage waters from the airport is very of COD in drainage waters from the airport is very low (0.003 ppm) at a location approximately 500 m from the airport, causing minimal change in COD concentration distributions in the marine area. Construction of this airport, designed as a key international airport in Japan, is being supervised as a national project. In Osaka Bay, land reclamation is strictly controlled by provisions in the Special Law for Environmental Conservation in the Seto Inland Sea. Special emphasis has been placed on preventing environmental Conservation in and on preventing environmental pollution in and around Osaka Bay, and conserving the natural environment in preparation of the airport plan, as well as in assessing environmental impact prior to construction. (Author's abstract)

EFFECTS OF LAND-USE BUFFER SIZE ON SPEARMAN'S PARTIAL CORRELATIONS OF LAND USE AND SHALLOW GROUND-WATER **OUALITY** 

Geological Survey, Trenton, NJ. L. E. Hay, and W. A. Battaglin.

Available from the US Geological Survey, Books and Open-File Reports Section, Federal Center, Box 25425, Denver, CO 80225-0425. Water-sources Investigations Report 89-4163, 1990. 28p, 8 fig, 6 tab, 21 ref

Significant correlations were observed between Significant correlations were observed between land use and shallow groundwater quality in the Coastal Plain of New Jersey. The strength of the correlation varies with the size of the land use buffer used for the analysis. Sets of circular buffers with 1-, 250-, 400-, 600-, 800-, 1,000-, and 1,200-meter radii were generated around 41 wells for which water quality data were available to determine the buffer size that maximizes these correlations. tions. A geographic information system was used to estimate the percentage of urban, undeveloped, and agricultural land within each circular buffer. Spearman's partial correlations were used to lessen closure effects and to minimize skewing of land use and water quality data distributions. The largest number of significant partial correlations (probability level < or = to 0.05) occurred between constituents and percent of urban land, with the effect of agricultural land removed. For this case, 13 of 35 constituents had one or more significant partial correlations. Nine of the 13 relations having signifi-cant correlations reached their maximum correlation value when land use was quantified within buffers with 800, or 1,200-meter radii. Significant-ly correlated variables showed a general pattern: partial-correlation magnitude tended to decrease monotonically as buffer size increased or decreased away from the size at which the maximum correlation occurred. LAND USE, WATER USE, STREAMFLOW CHARACTERISTICS, AND WATER-QUALITY CHARACTERISTICS OF THE CHARLOTTE HARBOR INFLOW AREA, FLORIDA.

Available from the US Geological Survey, Books and Open-File Reports Section, Box 25425, Feder-al Center, Denver, Co 80225-0425. Water-Supply Paper 2359-A, 1990. 64p, 26 fig, 29 tab, 106 ref.

Descriptors: \*Charlotte Harbor, \*Environmental effects, \*Florida, \*Hydrologic budget, \*Land use, \*Peace River, \*Water quality, \*Water resources development, \*Water use, Aquifers, Competing use, Groundwater resources, Human population, Surface-groundwater relations, Water demand, Water pollution sources.

Charlotte Harbor is a 270 sq mi estuarine system in west-central Florida. It is being subjected to increasing environmental stress by rapid population growth and development. The Charlotte Harbor inflow area includes about 4,685 square miles; the Myakka, the Peace, and the Caloosahatchee are the major rivers emptying into the harbor. Water use in the inflow area is about 565 million gallons per day (gpd), of which 59% is used for irrigation, 26% for industry, 11% for public supply, and 4% for rural supply. Total freshwater inflow from the three major rivers, the coastal area, and rainfall directly into Charlotte Harbor averages between 5,700 and 6,100 cu ft/sec, which is more than 3,500 directly into Charlotte Harbor averages between 5,700 and 6,100 cu ft/sec, which is more than 3,500 million gpd. A trend analysis of about 50 years of streamflow data shows a statistically significant decreasing trend for the Peace River stations at Bartow, Zolfo Springs, and Arcadia. In the Peace River, the decrease in flow may be related to a long-term decline in the potentiometric surface of the underlying Floridan aquifer system, which resulted from groundwater withdrawals. If this trend continues at the same rate, then excent for brief continues at the same rate, then, except for brief periods of storm runoff, the Peace River at Zolfo Springs could be dry year-round in about 100 years. Of the 114 facilities permitted to discharge domestic or industrial effluent to waters tributary domestic or industrial effluent to waters tributary to Charlotte Harbor, 88 are in the Peace River basin. Phosphate ore and citrus processing account for most of the industrial effluent. By 2020, the population in the inflow area is expected to increase by more than 500,000 people. They will require an additional 76 million gpd for water supply. The increased population will produce an additional 60 million gpd of domestic wastewater, which could result in an additional 3 tons per day of nitrogen and 0.65 ton per day of phosphorus. More than 150 square miles of land will be conmore than 130 square miles of fand will be converted to urban uses, which will produce another 0.25 ton per day of nitrogen from urban runoff. These increased nutrient loads can be expected to occur concurrently with decreased freshwater inflow. (Lantz-PTT)

AQUATIC MACROINVERTEBRATES OF THE ST. FRANCIS SUNKEN LANDS IN NORTH-EAST ARKANSAS.

A study was conducted to survey the aquatic macroinvertebrate diversity of the St. Francis Sunken Lands in northeast Arkansas. Secondary objectives were a determination of their relative abundance and distributional and seasonal patterns. adundance and distributional and seasonal patterns. Sixty semi-annual collections were made from 30 stations by sampling each station 2 times for 1.5 man-hours with a dip net. Totals of 243 taxa and 13,952 organisms were recorded for the sample period (August 1987-July 1988). Each station was

# Effects On Water Of Man's Non-Water Activities—Group 4C

assigned to 1 of 4 associations, distinguished by distinct physical factors within the river channels and immediate watershed. The Old River Channel-Oxbow Association exhibited the most complex and stable community structures; this was attributed to the relative lack of man's alteration of the habitat. The Channelized Ditches-Point Source Pollution Association demonstrated obvious detri-mental effects of man's intervention. The relatively simple community structures of the St. Francis Lake-Open Water Association were attributed to the typically homogeneous substrates of this area. The simplest community structures were in the Channelized Ditches-Intense Agriculture Associa-tion and were a direct result of man's multiple alterations within the river channels and immediate watershed. Seasonal species diversity indices and numbers of taxa varied inversely with respect to numbers of taxa varied inversely with respect to water level. High values occurred during low-water periods, whereas lower values occurred during high-water periods. This inverse relation-ship was attributed to flooded habitat, which led to population dilution and diminished collecting suc-cess. (Author's abstract) W91-10844

EFFECT OF LAND DEVELOPMENT ON GROUNDWATER RECHARGE DETERMINED FROM NON-STEADY CHLORIDE PROFILES. Queensland Dept. of Primary Industries, Brisbane (Australia). Soil Conservation Research Branch. Journal of Hydrology JHYDA7, Vol. 124, No. 1/ 2, p 43-58, April 1991. 6 fig, 3 tab, 28 ref.

Descriptors: \*Australia, \*Chlorides, \*Groundwat Descriptors: "Australia, "Chiorides, "Croundwai-er recharge, "Infiltration, "Land clearing, "Land management, "Land use, "Soil-water-plant rela-tionships, Acacia trees, Catchment areas, Crop-land, Model studies, Soil water, Solute transport, Vegetation effects.

The effect of clearing and subsequent crop and pasture growth on recharge to groundwater was investigated in three experimental catchments in the brigalow (Acacia harpophylla) lands of north-eastern Australia. Recharge was calculated from soil chloride data, using a simple transient solute mass balance model. Clearing had a substantial initial effect on groundwater recharge, with average recharge rates of 29-70 mm/yr in two cleared catchments, compared with 7 mm/yr in an uncleared catchment. These results were attributed to cleared catchment. These results were attributed to record high rains that fell while both cleared catchments were bare of vegetation, before crops or pastures were established. The effect was only or pastures were established. The effect was only short-lived, however, with no significant recharge occurring in any of the three catchments during the period in which crops and pastures were fully established. This lack of recharge was contrary to the general belief that clearing and establishment of crops or pastures causes a sustained increase in groundwater recharge. The low recharge rates at this site were attributed to the slowly permeable soils and the climate of the study site, where potential evaporation exceeds average rainfall in all soils and the climate of the study site, where poten-tial evaporation exceeds average rainfall in all months, and to the water use characteristic of brigalow. Brigalow is shallow-rooted, and at this site generated lower soil water deficits than either crops or pastures. Clearing is unlikely to result in high water tables in these soils under pastures or opportunity cropping systems under the average climatic conditions of the region. The simple tran-sient solute mass balance model used to estimate recharge rates gave important and significant difstent solute mass balance model used to estimate recharge rates gave important and significant differences in recharge when compared with a more commonly used steady-state model. All recharge rates calculated with the steady-state model were <1.8 mm/yr (most <0.3 mm/yr), and so this model could not identify the gross short-term recharge response to clearing at this site. EFFECTS OF CHANGES IN LAND USE ON ANNUAL STREAMFLOWS IN THE LAKE HURON BASIN OF CANADA AND THE UNITED STATES.

UNITED STATES.
Geological Survey, Reston, VA.
A. G. Scott, and R. B. Phinney.
IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 171-179, 3 fig,

Descriptors: \*Annual runoff, \*Environmental effects, \*International waters, \*Lake Huron, \*Land use, \*Streamflow, Agriculture, Canada, Deforestation, Precipitation, Rainfall-runoff relationships, Statistical analysis, United States, Urbanization.

Major changes in land use have occurred in the Great Lakes basin in Canada and the United States during the past several hundred years. Some of the documented changes include deforestation of large areas of agricultural uses, timbering for paper production, large increases in urbanized areas, development of recreational areas and home sites in rural areas, and installation of subsurface drainage for agriculture. These changes may have altered the runoff characteristics of the basin. Streamflow records for 10 gaging stations in the Lake Huron Basin for which annual streamflows were not sig-nificantly regulated were analyzed to determine trends in annual streamflows could be whether trends in annual streamflows could be identified once the variability of precipitation was taken into account. Length of record ranged from 31 to 71 years, and basin size ranged from 150 to 3,980 sq km. The streamflow records were analyzed by regressing annual mean streamflow against annual precipitation. The correlation between the regression residuals and time was quantified accordance and the streamflow and the strea tweet the regression residuans and time was quanti-fied nonparametrically by use of Spearman's rank-order correlation coefficient (rho) and tested for significant trends. A significant (p-level < 0.10) upward trend in streamflow was indicated for four sites, a downward trend at two sites, and no trend at four sites. Multiple-linear regression equations of the logarithm of annual mean streamflow as a function of the logarithm of annual precipitation and year were computed for each site. Annual mean streamflow was computed for the beginning and ending year of record for each site using these equations and the mean annual precipitation in the corresponding basin. An estimated average change in annual-mean streamflow, of 21%, was computed for the six tributary sites for which significant trends in annual streamflow were determined. This investigation indicates that changes in the hydroat four sites. Multiple-linear regression equations of investigation indicates that changes in the hydrologic response of these tributary basins to precipitation occurred concurrently with changes in land use or agricultural practices. The net annual release of carbon from tropical The net annual release of carbon from tropical forests of the world is estimated to range from 0.6 to 1.1 billion tons (Gt), based on computer model simulations. The simulations incorporate the most recent data on tropical land use change, regional differences in biomass and soil carbon density, and the conversion of forest to both shifting cultivation. and to permanent agriculture. Carbon accumula-tion in fallow and immature forests and in organic soil wetlands also is included. In general, biomass increases with temperature and moisture. Model simulations indicate that releases of 0.30 to 0.48 Gt/yr occur in South America, the region with the largest forest area, although deforestation rates are lower than the global average. In Southeast Asia, where mean regional forest biomass is high, carbon release rates range from 0.17 to 0.34 Gt/yr. The simulated releases are significantly lower those resulting from some earlier analyses which resulting from some earlier analyses which evaluated less detailed data on land-use change and carbon densities. The results suggest that tropical forests, when compared to fossi-hele sources, are presently a relatively small carbon source. Howevpresently a relativety small carbon source. However, understanding of the biosphere's role in the global carbon cycle requires further refinement in analysis of the many asynchronous regional carbon pools. CHANNEL TUNNEL AND ITS IMPACT ON THE FOLKESTONE AND DISTRICT WATER R. B. Monk.

Journal of the Institution of Water and Environ-

# Field 4—WATER QUANTITY MANAGEMENT AND CONTROL

# Group 4C-Effects On Water Of Man's Non-Water Activities

mental Management JIWMEZ, Vol. 5, No. 1, p 72-79, February 1991. 6 fig, 1 tab.

Descriptors: \*Aquifers, \*England, \*Pipelines, \*Tunnels, \*Water districts, \*Water supply, Drainage, Interagency cooperation, Saline water intrusion, Water distribution.

The construction of the Eurotunnel below the English Channel to connect England and France has had a marked impact on the operations of the Folkestone and District Water Company. The tunnel forms a conduit running through the Company's principal aquifer and into the sea. There is a possibility of drainage of the water from the aquifer and saline water intrusion into the aquifer from the sea. To supply the water demands of tunnel construction, numerous mains had to be constructed by the company and the tunnel siting also affected numerous mains, service reservoirs, spring overflows, and filter washwater drains. In addition, water supplies had to be constructed for the Cheriton rail terminal site. When tunneling operations began, movement in the Castle Hill landslip caused leakage from the water main in Castle Hill and movement of an adjacent steel gas main. Regular monitoring through observation boreholes will tell if the tunnel project has had any effect on the Chalk and Lower Greensand aquifers. Although the tunnel project has necessitated extensive but temporary additions to the distribution system, many possible uses can be made of the new pipelines. Close liaison between the water district and the tunnel project managers has facilitated tunnel construction and afforded numerous benefits and renovations to the water district. Journal of the Institution of Water and Environmental Management JIWMEZ, Vol. 5, No. 1, p 80-84, February 1991. 3 fig, 1 tab, 19 ref. Department of the Environment Contract PECD 7/7/170.

Descriptors: \*Herbicides, \*Nonpoint pollution sources, \*Path of pollutants, \*Pipelines, \*Simazine, \*Stream pollution, Agricultural runoff, Rainfall-runoff relationships.

Levels of simazine herbicide were measured in streams draining a small agricultural catchment after two successive rainfall events. The stage of the streams was recorded by weirs that triggered automatic samplers after rainfall events. Samples were analyzed for simazine by gas chromatography-mass spectrophotometry. Simazine was applied to hop yards within the catchment between 16 and 20 February 1889 at a rate of 1.7 kg/ha over a total area of 7.9 ha. Simazine had also been applied on 8 December 1988 to 5.7 ha of winter beans at a rate of 1.15 kg/ha. Results showed a delay of no more than 2 hr between rainfall commencement and entrance of the herbicide into the streams. The magnitude of simazine runoff decreased in the second rainfall event. The mean concentration during the first event was 29.5 micrograms/L and in the second only 8.1 micrograms/L The mass of pesticide accounted for in each of the events was 60.0 g and 0.6 g respectively, compared with a total application of 20.0 kg. This represented 0.3% of the total application for the first event and 0.05% for the second event. (Geiger-PTT) W91-11364

AGRONOMIC EFFECTS OF LAND APPLICA-TION OF WATER TREATMENT SLUDGES, Pennsylvania State Univ., University Park. Dept.

of Agricultural Engineering. H. A. Elliott, and B. A. Dempsey. Journal of the American Water Works Association JAWWA5, Vol. 83, No. 4, p 126-131, April 1991. 2 tab. 36 ref.

Descriptors: \*Agronomy, \*Environmental effects, \*Land disposal, \*Sludge disposal, \*Wastewater farming, \*Wastewater utilization, Boron, Copper, Fertilizers, Legal aspects, Liming, Manganese, Metals, Molybdenum, Nitrogen, Nutrients, Phosphorus, Sludge utilization, Zinc.

Economic, regulatory, and legal constraints on alternative disposal methods are raising interest in land application of water treatment sludges (WTS). A clear understanding of the agronomic and environmental effects is the first step toward implementing a land-based disposal option that will win regulatory approval and public acceptance. The chemical, physical, and biological characteristics of WTS determine its potential benefits and adverse effects on soil. WTS poses a less serious environmental threat than that posed by sewage sludge. However, aside from the iming capacity of softening sludges, the agronomic benefits of MTS, at least as a fertilizer, are fewer. The agronomic benefits of nitrogen in WTS depend more on its availability than on the total amount present. WTS can potentially correct soil deficiencies of iron and such micronutrients as boron, copper, manganese, zinc, and molybdenum. Phosphorus-fixing properties have been noted in WTS; this reduction in P mobility can be an asset when WTS is applied to soils with a high P pollution potential. Understanding the behavior and fate of metals in WTS-amended soils requires an evaluation of speciation, availability, and mobility. Waste handling methods at the treatment plant significantly affect ultimate disposal. A public relations effort is essential for a successful land application program. It is concluded that health and environmental risks are minimal from properly managed application of WTS to soils. (Doria-PTT)

BUDGETS OF SELECTED CATIONS AND ANIONS IN TWO FORESTED EXPERIMENTAL WATERSHEDS IN CENTRAL GREECE, Forest Research Inst., Athens (Greece).

Forest Research Inst., Athens (Greece). G. Nakos, and A. Vouzaras. Forest Ecology and Management FECMDW, Vol. 24, No. 2, p 85-95, 1988. 3 fig. 7 tab, 13 ref.

Descriptors: \*Land use, \*Forestry, \*Clearcutting, \*Environmental impact, \*Environmental chemistry, \*Forest watersheds, \*Cations, \*Anions, \*Greece, Potassium, Chlorides, Sodium, Sulfates, Nitrates, Nitrites, Ammonia, Calcium, Magnesium, Bicarbonates, Hydrogen ion concentration.

Concentration trends and budgets of selected ions dissolved in stream water were studied over four hydrological years in two forested experimental watersheds of central Greece, where Abies cephalonica was the dominant tree species. Weighted average annual concentrations (mg/L) of selected ions were: Ca(2+), 10.16; Mg(2+), 1.91; K(+), 0.77; Na(+), 4.45; Cl(-), 7.9; SO4(2-), 4.42; NH4(+)-N, 0.44; NO3(-)-N, 0.88; and pH, 7.26. Monthly concentrations of Ca(2+), Mg(2+), Na(2+) and HCO(3-) decreased with increasing rates of stream discharge up to a certain value, and thereafter remained almost constant. To the contrary, concentrations of J(+), Cl(-), SO4(2-), NH4(+)-N, like pH, were independent of rates of stream discharge. A 15% removal of the total standing volume did not change the concentrations, in stream water, of the selected ions. The data suggest that, annually, the experimental watersheds gained about 6 kg/ha or inorganic nitrogen and lost: Ca(2+), 56 kg/ha; Na(+), 34 kg/ha; Cl(-), 33 kg/ha; SO4(2-), 26 kg/ha; Mg(2+), 13 kg/ha; Cl(-), 3 kg/ha, (Author's abstract) W91-11550

IN: Watershed Development in Asia: Strategies and Technologies. World Bank Technical Paper No. 127. World Bank Publications, Washington, DC. 1990. p 1-34, 7 tab, 31 ref.

Descriptors: \*Asia, \*Environmental impact, \*Government supports, \*Water resources development, \*Watershed management, \*Watersheds, Agricultural watersheds, Developing countries, Economic aspects, Economic development, Land development, Management planning, Water resources management.

Land that can be defined as watershed in Asia is a significant proportion of the total land. These watersheds suffer such problems as loss of agricultural productivity due to erosion, deforestation, population pressure and poverty, sedimentation of infrastructure downstream, flooding, and erratic streamflows. The main themes emerging from analyses of watershed problems involve typical policy responses by governments and multilateral and bi-lateral donors, and the insufficient evolution of conservation technology. The rationale for a watershed management approach must be examined in the context of physical, economic, and political linkages, taking into account the interplay between upland and lowland areas. In proposing how investments may be made to solve watershed problems, a case can be made that the most technically and economically efficient approach would focus on site-specific technologies that are environmentally benign. Specific actions that development agencies should pursue in their operations and in discussions with governments include structural treatments, vegetative/cultural measures, investment in nonarable areas, and treatment of forest areas. The problem-solving approach should take into account the folly of a single solution, the importance of planning at a micro level, and a menu of solutions. Incentives for participation in watershed development may include land tenure, profitability of the farming system, and economicatus for the participants. Recommended approaches to watershed development need to address flooding and sediment, cost sharing and cost recovery, rural infrastructure, analytic methods, guidelines, funding procedures, and the need for commitment. SOIL AND MOISTURE CONSERVATION TECHNOLOGIES: REVIEW OF LITERATURE. International Bank for Reconstruction and Development, Washington, DC. Agriculture Div. J. B. Doolette, and J. W. Smyle. IN: Watershed Development in Asia: Strategies and Technologies. World Bank Technical Paper No. 127. World Bank Publications, Washington, DC. 1990. p 35-69, 6 tab, 221 ref.

Descriptors: \*Agricultural watersheds, \*Asia, \*Literature review, \*Soil conservation, \*Soil water, \*Water conservation, \*Water resources water, water conservation, water resources management, Agricultural engineering, Climatic zones, Developing countries, Erosion, Farm management, Productivity, Sedimentation, Soil treatment, Surface runoff, Water resources develop-

The World Bank has financed many projects with substantial watershed development components. This substantial investment, combined with the Inis substantia investment, combined with the sizable commitment implicit in projects under preparation, prompted regional staff to question the technologies and treatments from the standpoint of efficacy, synergism, the benefits accruing from them, and relative cost and replicability. Research literature has been reviewed concerning onsearch interature has been reviewed concerning on-farm impacts of soil and moisture conservation technologies on surface runoff, erosion/sedimenta-tion and productivity and yield. The review in-cludes data from more than 200 studies globally that appear to be based on valid experimental methods. The literature regarding the impact on soil moisture and surface runoff may be categorized as clearing land for agriculture, vegetative and cultural measures (grass cover and strips, and cultural measures (grass cover and strips, mulching, cultivation practices, contour cultivation, ridge and furrow), and structural measures (earth banks, land leveling, and terraces). The effect of treatments on erosion rates and sediment yields is arranged by climatic zones, e.g., equatorial monsoon, continuously wet tropics, dry/wet monsoon, wet and dry tropics, temperate zone, semi-arid tropics, and semi-arid temperate zone. Causes of productivity decline are soil moisture loss, soil nutrient loss, and organic matter. Soil treatments include cover, clearing of land, tillage, contour cultivation and ridging, vegetative barriers treatments include cover, clearing of land, tillage, contour cultivation and ridging, vegetative barriers on key contour lines, ripped furrows, construction of banks, land leveling, and terracing. There are limitations to extrapolating from the data to other sites and projects, due to lack of standardized methodologies and limited quantitative data. A need is seen for sound results from well-designed and properly equipped experiments, and for expansion of the types and ranges of experiments to cover the extreme situations experiments to cover the extreme situations experienced by small farmers. ECONOMIC ANALYSIS OF SOIL CONSERVA-TION TECHNOLOGIES.

International Bank for Reconstruction and Development, Washington, DC. Environmental Policy

Research Div W. B. Magrath.

In: Watershed Development in Asia: Strategies and Technologies. World Bank Technical Paper No. 127. World Bank Publications, Washington, DC. 1990. p 71-96, 7 fig, 9 tab, 18 ref, 2 append.

Descriptors: \*Agricultural engineering, \*Agricultural runoff, \*Asia, \*Erosion control, \*India, \*Productivity, \*Soil conservation, \*Soil erosion, Cropyield, Developing countries, Earthworks, Economic aspects, Grasses.

It is widely accepted that erosion lowers agricultural productivity and that soil conservation raises and preserves it. However, there is little agreement on exactly how productivity is related to erosion or on the quantitative impact of erosion on yields. Nor is there widespread agreement on how erosion influences the accompany of agricultural productions. Nor is there witespread agreement on now crosson influences the economics of agricultural production. In view of these difficulties, an engineering economics approach is most practical: the impacts of erosion and conservation are applied to an economic model of crop production and the value of

conservation is calculated on the basis of a with-without comparison. The relative economic advantages of a conservation system based on vetiver grass (Vetiveria zizanioides) was explored by comgrass (Vetiveria zizanioides) was explored by comparison with the more conventional approach of constructing earthen bunds, using data reflecting conditions in India. By interrupting the length of the field, both techniques are intended to slow movement of water down the slope; however, vetiver grass hedges eventually form terraces, and earthen bunds are designed to channel surplus water into drains. The results of the basic analysis showed that both systems appear economically viable using base case assumptions. However, due to its speculative nature, modeling of a range of plausible combinations of parameters was performed. It was found that the dominance of vetiver grass technology is essentially complete for any tormed. It was round that the dominance of vertiver grass technology is essentially complete for any plausible combination of parameters, mainly due to the cost advantage of vetiver grass. For instance, vetiver grass with a net present value of Rs 8,543/ha (IRR=95%) is clearly superior to bunding (NPV=Rs 3,436/ha, IRR=28%). It may be concluded that, despite obvious gaps in knowledge, a structured analysis of soil conservation investments. structured analysis of soil conservation investments can generate useful insights, and perhaps most usefully, can highlight specific issues on which additional research is necessary. There is an obvious need for more reliable cost data on crop production and a better understanding, both technical and economic, of farmers' responses to erosion. (See also W91-11563) (Fish-PTT)

ECONOMIC ANALYSIS OF OFF-FARM SOIL

CONSERVATION STRUCTURES.

International Bank for Reconstruction and Development, Washington, DC. Environmental Policy

Nesteated Dev.

B. Magrath.

IN: Watershed Development in Asia: Strategies and Technologies. World Bank Technical Paper No. 127. World Bank Publications, Washington, DC. 1990. p 97-107, 1 fig, 9 tab, 9 ref.

Descriptors: \*Check dams, \*Cost-benefit analysis, \*Economic aspects, \*Hydraulic structures, \*Soil conservation, Developing countries, Economic evaluation, Erosion rates, Hydraulic engineering, Indonesia, Irrigation, Silting.

Although off-farm structures such as check dams Attnough off-arm structures are often a sub-stantial portion of costs in watershed projects, they are seldom subjected to benefit-cost analysis, due to their typically small size and dual objective of providing environmental and productive benefit. A benefit-cost analysis was performed based on data collected in Indonesia for a representative check dam. Regression analyses of average values and construction cost, and sensitivity analyses of ner present values to construction costs were conductconstruction cost, and sensitivity analyses of net present values to construction costs were conduct-ed. It was found that, for all combinations, higher erosion rates (or shorter life spans) yield higher returns, due to the earlier onset of land reclamation benefits. It was concluded that a rudimentary analysis can help distinguish viable investments from unprofitable ones, even when values for environmental benefits are uncertain. Furthermore, the effort required for benefit-cost analysis is minimal, compared to the engineering and construction input. Also noted are some strategic considerations involved in evaluating off-farm structures for watershed projects, such as requiring implementing agencies to include simple economic analysis in the planning of such structural works, and to consider the economic productivity of small structures in relation to cost. (See also W91-11563) (Fish-PTT) W91-11567 mental benefits are uncertain. Furthermore, the

REVEGETATION TECHNOLOGIES.

A. K. Banerjee.

IN: Watershed Development in Asia: Strategies
and Technologies. World Bank Technical Paper
No. 127. World Bank Publications, Washington,
DC. 1990. p 109-129, 1 tab, 16 ref.

Forest management, Grasses, Reforestation, Shrubs, Trees.

Revegetation is a significant technology employed in the rehabilitation of upper watersheds in the Asia region. It traditionally encompasses both enrichment planting and forestation of bare areas. However, much plantation work has been less successful than hoped, due to both technical and nontechnical reasons. A review of available technology reveals a number of shortcomings: choice of secritic has overembasized trees excitics. of species has overemphasized trees, exotics, and monoculture; the introduction of shrubs, indigemonoculture; the introduction of shrubs, indige-nous legumes and grasses, on the contour as a hedge, should find a place in land stabilization and the regeneration of vegetation. Ground prepara-tion includes removal of ground vegetation, win-drowing, burning, and soil manipulation. In plant-ing methods, reintroduction of direct sowing and more use of bare-root planting and biodegradable containers to reduce cost are proposed. In planting design, it is suggested that planting with a shrub hedge on the contour; in between the tree rows hedge on the contour in between the tree rows should replace the present method of square planting. Regarding protection, social consent with watch and ward or with a live hedge raised at least two years in advance is preferable to other forms of fencing. Management of revegetated areas presof fencing. Management of revegetated areas presently comprises two methods: complete protection without any harvesting and regular harvesting at the rotation age. Both methods fail to consider the needs of local villagers for a continuous supply of products. This can be satisfied by introducing silvicultural practices such as annual brashing, low and high pruning and topping of the hedge, and thinning of the top canopy of trees. There is a critical need for active participation by local inhabitants in revegetation programs, which is now often lacking. (See also W91-11568) (Fish-PTT)

Ethoxyresorufin O-deethylase (EROD) is a mixed function oxidase which is supported by induced forms of cytochrome P-450. These isoforms are induced in natural environments by polycyclic aroinduced in natural environments by polycyclic aro-matic hydrocarbons present in petroleum and by polychlorinated biphenyls (PCBs). The EROD assay was adapted to the microplate technique and conditions for optimal measurements were studied in several species useful in a monitoring system. A simplified procedure was developed for the prepa-ration and fluorimetric assay of EROD activity using only basic laboratory equipment. In addition

#### Group 5A-Identification Of Pollutants

to reproducibility of results and a good sensitivity to reproducionity of results and a good sensitivity identical to that of the classical cuvette technique, the greatest advantage to using microplate readers is the rapidity of the measurements. This permits multiple simultaneous assays and thus long kinetic studies which are of interest for measuring low stibilities and avoiding intercrution of the actions of the actions. studies which are of interest for measuring fow activities and avoiding interruption of the acetone reaction. It was possible to automate the technique, distribution of reagents, and processing of data. The method was used to determine EROD activity in plaice, flounder, and eel. The microplate read technique was twice as sensitive as the classic cuvette reader for the EROD activity assay. With the plate reader the coefficient of variation was less than 7%. In the context of biological monitor-ing, especially of PAH and PCBs, the direct ing, especially of PARI and PARI and PEROD activity assay using the microplate reader technique combines the advantages of simplicity and rapidity which are essential to such surveillance projects. # GROWTH POTENTIALS OF RED TIDE PHY-TOPLANKTERS IN COASTAL SEAWATER BY AGP ASSAY.

Kochi Univ. (Japan). Faculty of Agriculture. T. Nishijima, and Y. Hata. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 175-179, 1991. 3 fig, 7 tab, 5 ref.

Descriptors: \*Algal growth, \*Bioassay, \*Coastal waters, \*Phytoplankton, \*Pollutant identification, waters, \*Phytoplankton, \*Pollutant identification, \*Red tide, Culturing techniques, Japan, Limiting nutrients, Nitrogen, Osaka Bay, Phosphorus.

Preparation of algal inocula for algal growth po-tential (AGP) was investigated. Using two red tide phytoplankters, and growth potentials and growth-limiting nutrients of red tide phytoplankters were evaluated in coastal waters of Osaka Bay, Japan. evaluated in constal waters of Osaka bay, Japan. The red tide phytoplankters Heterosigma akashiwo and Skeletonema costatum were used as assay organisms. When using AGP assays, the growth potentials were dependent on the preparation of the algal inoculum. Accurate growth potentials were obtained only when sufficiently nutrient-starved cells were inoculated into the samples. Insufficient starvation of the cells resulted in an overestimation of growth potential. Based on the overestimation of growth potential. Based on the results of the assay, the growth potentials of Osaka Bay water were about 10,000 cells/ml for Heterosigma akashiwo and about 100,000 cells/ml for Skeletonema costatum. Moreover, the water had the potential to develop to a red tide population density for both species. The limiting nutrients for both red tide phytoplankters were nitrogen and phosphorus. # MARINE POLLUTION BIOASSAY BY USING SEA URCHIN EGGS IN THE TANABE BAY, WAKAYAMA PREFECTURE, JAPAN, 1970-1987.

Doshisha Univ., Kyoto (Japan). Biological Lab. N. Kobayashi.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 709-713, 1991. 1 fig, 1 tab, 4 ref.

Descriptors: \*Bioassay, \*Echinoderms, \*Japan, \*Pollutant identification, \*Tanabe Bay, Antifoulants, Bioaccumulation, Juvenile growth stage, Marine pollution, Mortality, Organotin compounds, Seasonal variation.

The results of eighteen years of bioassays of the water at the Seto Marine Biological Laboratory and around Hatakejima Island, Shirahama, and Wakayame Prefecture, are reported. Eggs and sperm of Hemicentrotus pulcherrimus and Pseudosperm of Hemicentrotus pulcherrimus and Pseudo-centrotus depressus were used as bioassay orga-nisms. During 1982 and 1987, very polluted water was found around Hatakejima Island and Tsuna-shirazu Cove in early autumn to winter. As these phenomena differed from the tendency of polluted water to occur mainly in summer, the cause was, most probably, tributyltin oxide, a biocide used in the paint on the fish rearing cages in the area. MICROBIOLOGICAL METHODS FOR SAFETY TESTING OF DRINKING WATER DI-RECTLY RECLAIMED FROM WASTEWATER. Pretoria Univ. (South Africa). Dept. of Medical

Wirology. W. O. K. Grabow, R. Kfir, and J. L. Slabbert.
Water Science and Technology WSTED4, Vol.
24, No. 2, p 1-4, 1991. 15 ref.

Descriptors: \*Bioassay, \*Bioindicators, \*Drinking water, \*Microbiological studies, \*Pollutant identification, \*Toxicity, \*Wastewater renovation, \*Water quality monitoring, \*Water reuse, Ames test, Bacteria, Bacteriophage, Carcinogenicity, Chemical analysis, Coliforms, Culturing techniques, Enzymes, Epidemiology, Growth media, Mutagenicity, Namibia, Performance evaluation, Pseudomonas, Salmonella.

Microbiological methods were assessed for the testing of drinking water directly reclaimed from wastewater at an advanced multiple-barrier reclamation system in Namibia. The safety of the water could be monitored reliably by such practical indi-cators as standard plate counts, coliform bacteria, coliphages, and acid-fast bacteria. A convenient plate incorporation modification of the Ames Salmonella mutagenicity assay proved suitable for routine quality surveillance of potentially carcino-genic and mutagenic compounds; results were con-firmed by comparative tests using a hamster em-bryonic cell transformation assay in which sensitivoryonic cell transformation assay in which sensitivity was increased by preparing growth media from test water. Screening for toxic activity was done reliably by assays based on interference with the multiplication of Pseudomonas putida, the cloning efficiency of BGM, HeLa, and mouse lymphoma cell lines and activity of the enzyme urgase. A cell lines, and activity of the enzyme urease. A commercial limulus amebocyte lysate assay proved a reliable and sensitive method for the detection of endotoxins. Correlation with results obtained in sophisticated chemical analyses, as well as long-term epidemiological studies on consumers, conterm epidemiological studies on consumers, con-firmed that, subject to the maintenance of certain operational conditions, the safety of directly re-claimed water could be monitored by relatively simple, inexpensive, and rapid microbiological tests and bioassays. #### EC BATHING WATER VIROLOGICAL STAND-ARD: IS IT REALISTIC.

Severn-Trent Labs., Coventry (England). Water Science and Technology WSTED4, Vol. 24, No. 2, p 49-52, 1991. 3 tab, 3 ref.

Descriptors: \*Europe, \*European Economic Community, \*Public health, \*Recreation, \*Swimming, \*Viruses, \*Water analysis, \*Water pollution management, \*Water quality monitoring, \*Water qualagement, water quanty monitoring, water quarty ity standards, Analytical techniques, Bacteria, Bioindicators, Contamination, Enteroviruses, Human diseases, International agreements, Pathogens, Sampling, Standards, Wastewater.

The European Community (EC) directive on bathing water defines a viral standard of nil in 10 liters but does not recommend the means by which viruses should be concentrated and detected. The viruses should be concentrated and detected. In edirective's standard for viruses is mandatory, requiring a 95% compliance level in the waters during the bathing season. As yet no virological monitoring is carried out in such a way as to comply with the 95% pass rate required by the directive. While viruses can be detected in any waters that receive sewage discharges, there is growing evidence that the use of the bacterial indicator system to indicate health risk and virus presence is faulty. Virus methodologies are currently limited to the determination of culturable renty inflined to the determination of culturable enteroviruses and rotavirus. There are no methods for the known waterborne pathogens such as hepatitis A and Norwalk-type viruses. This does not allow for the assay of total virus content, the

present zero standard for enteroviruses thus being only a likely minimum measure of virus contamina-tion. One possibility for altering the standard is to reduce the implied compliance level of 95% to 80%, which would give a virus sample in each month of the (British) bathing season of May to September. Another possibility is to categorize waters according to the type of recreation that would be acceptable in terms of exposure to vi-ruses. Until there is clear evidence to indicate that the risk is at least acceptable for the recreational activity proposed, the EC standard should remain. (See also W91-10612) (Doria-PTT) W91-10622

# PRODUCTION AND CONTROL OF REFERENCE MATERIALS FOR WATER MICROBI-

Rijksinstituut voor de Volksgezondheid en Milieu-hygiene, Bilthoven (Netherlands). Lab. for Water

hygiene, Buthoven (vecineriands). Lab. 10 Mars and Food Microbiology. K. A. Mooijman, A. H. Havelaar, J. A. Hoekstra, and N. G. W. N. van Strijp-Lockefeer. Water Science and Technology WSTED4, Vol. 24, No. 2, p 53-56, 1991. 4 fig, 2 ref.

Temperature.

The use of standard methods for microbiological analysis of water does not guarantee consistent results in different laboratories. Therefore, reference materials for water microbiology were pre-pared by spray-drying milk artificially contaminated with a known test strain. The resulting highly contaminated milk powder was mixed with sterile milk powder to a contamination level of 2,000-3,000 cfu/g. Gelatin capsules were filled with the mixture (0.2 g/capsule) to produce the reference materials. Test strains used were: WR1 Escherichia coli, WR3 Enterobacter cloacae, WR63 Enterocon, wks Enteropacter cloacae, wkos Entero-coccus faecium, and WR51 Staphylococcus sp. Optimization of the mixing procedure and aging of the highly contaminated milk powder for at least one year resulted in relatively homogeneous and stable reference materials. Short-term challenge tests at 'high' temperatures (30 and 37 C) may be tests at 'nign' temperatures (30 and 37 C) may be predictive for long-term stability at 'low' temperatures (4 to 6 C). Reference materials with strain WR3 were stable for one week at 30 C and for at least 6 months at 4 to 6 C. Possible applications of the reference materials include quality control of routine measurements, comparison of the efficiency of different culturing methods, and as a standardized sample in collaborative studies. Water Science and Technology WSTED4, Vol.
24, No. 2, p 89-93, 1991. 6 tab, 14 ref.

Descriptors: \*Bacterial analysis, \*Drinking water, \*Iraq, \*Pollutant identification, \*Water analysis, \*Water quality monitoring, \*Well water, Aerobic bacteria, Bacteria, Basrah, Biochemical oxygen demand, Chlorides, Coliforms, Culturing techniques, Dissolved oxygen, Fecal bacteria, Filtration, Heterotrophic bacteria, Hydrogen ion concentration, Temperature, Water pollution sources.

A survey of heterotrophic aerobic bacteria, total coliforms, fecal coliforms, and fecal streptococci was performed on water samples from 32 wells in the desert west of Basrah (Iraq). Physical and chemical parameters were as follows: temperature 26-28 C; pH 7-8.4; and dissolved oxygen 3.7-5 mg/L. Correlation coefficient values between total viable count (TVC) and physical or chemical parameters suggested that TVC was not correlated with any environmental variables tested. Fecal contamination of wells was mostly of animal sources as indicated by the low ratio of fecal coliforms to fecal streptococci. Four methods were used to enumerate the bacteria: spreading, membrane filtration, repair detection, and replica plating. The last method was most accurate, especially for detecting injured cells. Fecal coliforms ranged ing. Ine last method was most accurate, especially for detecting injured cells. Fecal coliforms ranged from 5 to 280 cfu/ml. Biochemical oxygen demand of the well water was 0.6-1.5 mg/L, and chloride content of wells was 354-1,240 mg/L. It is concluded that Basrah well water should be purified before drinking. RELATIONSHIP BETWEEN PSEUDOMONAS AERUGINOSA AND BACTERIAL INDICA-TORS IN POLLUTED NATURAL WATERS.

Malaga Univ. (Spain). Facultad de Ciencias. A. de Vicente, J. C. Codina, and P. Romero. Water Science and Technology WSTED4, Vol. 24, No. 2, p 121-124, 1991. 1 fig, 2 tab, 12 ref.

Descriptors: \*Bacterial analysis, \*Bioindicators, \*Path of pollutants, \*Pseudomonas, \*Water quality monitoring, Bacteria, Fecal coliforms, Fecal strep-tococci, Malaga, Rivers, Seawater, Spain, Wastewater, Water pollution, Water pollution

The relationship was established between Pseudomonas aeruginosa and the fecal pollution index (total coliforms, fecal coliforms, and fecal strepto-cocci) in natural waters. Water samples were collected from several aquatic environments in Malaga (Spain). Pseudomonas aeruginosa counts Malaga (spain). Fseudomonas aeruginosa counis and isolation frequencies were clearly associated with the degree of fecal pollution of the water. Results confirmed that domestic sewage was the major source of P. aeruginosa in river water and seawater, being isolated from sewage at concentrations of about 100,000 cfu/100 ml. There was a close correlation between the P. aeruginosa con-centration and the densities of the three fecal indicators in both river and marine waters. A significant correlation was not observed in waters with little fecal pollution, because P. aeruginosa was isoleted from these materials. isolated from these waters only occasionally and at very low densities. Pseudomonas aeruginosa con-centrations in sewage and polluted natural waters were generally 3-4 log lower than the total coliform (TC) densities and 2 log lower than fecal coliform (FC) and fecal streptococci (FS) concentrations. TC, FC, and FS could be considered adequate indicators of the presence and densities of P. aeruginosa in natural waters, especially TC in fresh water and FS in seawater, as these parameters showed the best correlations and the most parallel inactivation processes with P. aeruginosa in each environment. A miniaturized fluorogenic assay was developed as a rapid and easy procedure for the enumeration of fecal indicators in seawater. To detect Escherichia fecal indicators in seawater. To detect Escherichia coli, 4-methylumbelliferyl beta-D-glucuronide (MUG) was incorporated into a modified Al broth. To detect enterococci, 4-methylumbelliferyl broth. To detect enterococci, 4-methylumbelliferyl beta-D-glucoside (MUD) was incorporated into a selective medium. To each well of a sterile 96-well microtitration plate, 100 microL of media was added, air-dried, covered with sterile tape, and stored at 4 C. To enumerate the indicator bacteria, 200 microL of diluted or undiluted water was added to wells with MUG and MUD media. The plates were incubated for 36-40 hours at 44 C and observed in the dark for fluorescence by ultraviolation of the control of the subsurface margine, water better the control of the subsurface margine, water better the control of the cont let light (366 nm). Fifty subsurface marine waters from four areas were examined. The recovery rate from four areas were examined. The recovery rate of the fluorogenic assays is equal or superior to 3-tubes must probable number (MPN) and membrane filtration (MF). The microtitration plate with MUG is more specific for E. coli than the membrane filtration. An 87.4% confirmation rate was ved with the fluorogenic assay compared to a 6 false-positive rate with membranes. For the observed with the fluorogenic assay compared to a 31.7% false-positive rate with membranes. For the enterococci, the analysis of 23 English Channel and North Sea samples indicated that the fluorogenic assay and the standard methods had the same specificity. In contrast, the microtitration plate with MUD showed by far the best specificity on 13 Mediterranean samples. A 100% confirmation rate was observed with the fluorogenic assay, while 44% and 63% false-positive rates were observed with 3 tubes MPN and MF respectively. Descriptors: \*Bacterial analysis, \*Culturing techniques, \*Legionella, \*Most probable number test, \*Pathogenic bacteria, \*Pollutant identification, \*Water analysis, Agars, Bacteria, Coliforms, Filtration, Fluorescence, Incubation, Membrane process-

A new quantitative method was developed for the enumeration of Legionella bacteria. Appropriate tenfold serial dilutions of water samples concentrated by membrane filtration are plated in triplicate on buffered charcoal yeast extract agar. After incubation for 3 days, representative smears from individual plates are tested for the presence of Legionella by direct fluorescent antibody (DFA) staining. The number of positive plates in each dilution is used to calculate the Legionella count by means of conventional most probable number statistics. In comparative tests on a variety of by means of conventional most probable number statistics. In comparative tests on a variety of water samples, the new method yielded significantly more positive results than the previously used method. A typical example is a series of 18 comparative tests on mine service waters that were of poor quality on the basis of heterotrophic plate and coliform counts. DFA staining tests on the original concentrates yielded positive results for all the samples. Fifteen of these samples (83%) yielded positive results by the new method, while legionellae were detected in only five (28%) of the samples using the old method. Apart from recovering more Legionella bacteria and yielding higher counts, the new method is quantitative and is less expensive, cumbersome, and time-consuming, yielding results in 3 instead of 14 days. ISOLATION AND IDENTIFICATION OF CRYPTOSPORIDIUM FROM WATER.

Thames Water Authority, London (England). G. Vesey, and J. Slade. Water Science and Technology WSTED4, Vol. 24, No. 2, p 165-167, 1991. 2 fig, 6 ref.

Descriptors: \*Cryptosporidium, \*Isolation, \*Parasites, \*Pollutant identification, \*Protozoa, \*Public health, Centrifugation, Filters, Filtration, Flocculation, Immunoassay, Membranes, Microscopy, Performance evaluation, Water analysis.

The efficiency of the established method for isolation and identification of Cryptosporidium was assessed. Detection of oocysts in water relies upon filtration of large volumes of water and examination of the concentrate by microscopy. An immunofluorescent assay using monoclonal antibodies specific to the outer wall of the cocysts is applied to the concentrate which is then examined with to the concentrate, which is then examined with an epifluorescent microscope. Recovery by these methods was found to be as low as one percent. Each stage of the process was studied to determine where the loss of oocysts occurs. It was found that where the loss of occysts occurs. It was found that between 5 and 30 percent of the occysts were not retained by the initial cartridge filtration. A further 2 to 30 percent could not be eluted. Subsequent stages involving centrifugation and ultrasonic disstages involving centrifugation and ultrasonic disaggregation were shown to disrupt staining by the established immunofluorescence assay; the epitopes to which the monoclonal antibodies are specific appear to be damaged by the shear forces generated during centrifugation. It is concluded that the established method vastly underestimates the number of Cryptosporidium occysts in water. The microwynd filters currently used do not appear to be as effective as previously reported. Intital results using various pleated membranes have been promising. An alternative to centrifugation is obviously required. Investigations into a flocculation ously required. Investigations into a flocculation technique to concentrate samples are in progress. Raw sewage samples were collected monthly for one year from 11 wastewater treatment plants across the United States. Giardia cyst concentraacross the United States. Giardia cyst concentra-tions were determined by direct count and the data adjusted based on percentage of industrial wastewater processed by each plant. Although dif-ferences in the adjusted annual geometric mean cyst concentrations were noted among the sites (range 683-3,750 cysts/L), there was no correlation of cyst concentration with geographical location as determined by either latitude or longitude. However, when the three southermost sites were grouped and compared to all remaining sites, there was a significant difference in the annual geometric mean cyst concentration, with the southermost sites being higher. There was no significant association of geometric mean cyst concentration with size of the wastewater treatment plant as represented by mean daily flow. Attempts were made to obtain and correlate giardiasis cases with the monthly cyst levels at each of the sites. Due to reporting problems, low number of cases, and unavailability of data, case information was deemed usable for only four sites. A significant positive correlation with cases in the community was found at one site. Lack of correlation at other sites was believed to be due to deficiencies in case reporting. Results suggest that sewage examination may be useful for surveillance of Giardia infections in the community. (See also W91-10612) (Author's abstract) W91-10646

IMPROVEMENT OF THE ZETA-PLUS FILTER METHOD FOR CONCENTRATION OF VI-RUSES FROM WATER. Tokyo Metropolitan Research Lab. of Public

Health (Japan). K. Yano, Y. Yoshida, and M. Kaneko.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 217-220, 1991. 6 tab, 6 ref.

Descriptors: \*Filtration, \*Japan, \*Pollutant identification, \*Sampling, \*Viruses, \*Water analysis, Anions, Cellulose, Drinking water, Performance evaluation, Preconcentration, Rivers, Sample prep-

Factors affecting the condensation of viruses from river water by zeta-plus filters were studied with the aim of improving the virus detection method. Samples were taken from rivers in Tokyo (Japan). Samples were taken from rivers in Tokyo (Japan). Supplementation of anion-charged diethylaminoethyl-cellulose was used to promote the adsorption of viruses onto the filter. Maximum recovery rate (54.0%) was obtained with a virus concentration of 5,390 pfu/ml, DEAE-cellulose of 0.5%, and

a sample volume of 1,000 ml. The minimum recovery rate (11.4%) was obtained with a virus concentration of 53 pfu/ml, DEAE-cellulose of 0%, and a tration of 35 ptm/ml, DEAE-cellulose of 0%, and a sample volume of 1,000 ml. Addition of cellulose to the water to give a concentration 0.5% resulted in an increase of 21.59% in the recovery rate. The DEAE-cellulose may react with substances in water that disturb the adsorption of viruses; therefore, supplementation with cellulose is unnecessary when the filter method is applied to 'clean' (e.g., finished) waters. (See also W91-10612) (Doria-PTT) W91-10655

ROTAVIRUS DETECTION: A PROBLEM THAT NEEDS CONCENTRATION. Thames Water Authority, London (England).

National Technology WSTED4, Vol. 24, No. 2, p 221-223, 1991. 6 ref.

Descriptors: \*Flocculation, \*Immunoassay, \*Pol-lutant identification, \*Rotaviruses, \*Sample prepa-ration, \*Sampling, \*Ultrafiltration, \*Viruses, \*Water analysis, Adsorption, Comparison studies, Fluorescence, Preconcentration, Shear, Sugars.

Three candidate second-step concentration methods were assessed for the routine detection of rotavirus: organic flocculation, ultrafiltration, and hydroextraction. Virus recovery from each of the methods was quantified by an immunofluorescence methods was quantified by an immunofluorescence assay. After initial adsorption of virus onto a nitro-cellulose filter and subsequent elution with 3% beef broth, organic flocculation gave an average recovery of 4%. Ultrafiltration gave an average recovery of 48%, while hydroextraction in crystalline sucrose gave a recovery rate of 60%. Results suggest that hydroextraction with crystalline sucrose is a very efficient method for the concentration of rotavirus compared to the creamic flocculation of rotavirus compared to the organic flocculation method. Ultrafiltration also showed prom results, although possible disadvantages may be the development of shearing forces and blockage of the filter. Routine detection of rotavirus by the hydroextraction method would produce a result in 3 days; ultrafiltration would give a result in 2 days, but with decreased sensitivity. Possible disadvan-tages of hydroextraction would be aggregation of viruses and the retention of toxic compounds. (See also W91-10612) (Doria-PTT) W91-10656

RECOVERY OF ENTEROVIRUS FROM PRI-MARY SLUDGE USING THREE ELUTION CONCENTRATION PROCEDURES.

Nancy-1 Univ. (France). Faculte de Pharmacie. M. Albert, and L. Schwartzbrod. Water Science and Technology WSTED4, Vol. 24, No. 2, p 225-228, 1991. I fig, I tab, 9 ref.

Descriptors: \*Enteroviruses. \*Pollutant identification, \*Sludge analysis, \*Viruses, Adsorption, Floc-culation, France, Nancy, Preconcentration, Sample preparation, Water analysis

Recovery virus from sewage sludge is usually per-formed by elution of adsorbed virus with an alkaline solution, followed by concentration, before inoculation on cell cultures. Three extraction-concentration procedures were compared using 40-g pellets of solid-fraction sludge prepared from liquid primary sludge from the wastewater treat-ment plant at Nancy (France). Concentrates were ment plant at Nancy (France). Concentrates were assayed using the agar overlay plaque formation technique with inoculation of MA 104 continuous cell line. The highest virus recovery was obtained by elution with 3% beef extract/0.1 M borate buffer at pH 9 together with polyethyleneglycol precipitation as a concentration step. Heterogene-ous and lower results were obtained with elution by a 1% skim milk solution (pH9) or a 0.05 M glycine solution (pH 9) and concentration by organic flocculation. (See also W91-10612) (Doriaganic PTT) W91-10657

CONCENTRATION OF HEPATITIS A VIRUS IN ENVIRONMENTAL SAMPLES, Barcelona Univ. (Spain). Dept. of Microbiology.

A. Bosch, R. Gajardo, F. X. Abad, J. M. Diez, and J. Jofre. Water Science and Technology WSTED4, Vol. 24, No. 2, p 229-234, 1991. 5 tab, 12 ref.

Descriptors: \*Hepatitis A virus, \*Pollutant identification, \*Sample preparation, \*Sampling, \*Viruses, \*Wastewater analysis, \*Water analysis, Adsorp-tion, Assay, DNA, Drinking water, Filters, Floc-culation, Freshwater, Human diseases, Preconcentration. Seawater.

The cytopathogenic pHM-175 strain of hepatitis A virus (HAV) was used to develop different procedures for the concentration of HAV in tap water, fresh water, seawater, and raw sewage. HAV was quantified by a plaque assay in the FRhK-4 cell line. Water samples were concentrated by a modification of the adsorption to and elution from the glass powder (GPAE) method, by adsorption to and elution from filter aid, and by ammonium sulfate flocculation (ASF). The GPAE method consistently yielded greater HAV recoveries than filtration through filter aid or ASF. HAV was concentrated by GPAE from 20-liter samples with satisfactory efficiencies in all kinds of water: 100% for tap water, 80% for freshwater, 75% for seawater, and 61% for sewage. Concentration efficiencies for filter aid and ASF were always lower than 25% and 40%, respectively, in any kind of The cytopathogenic pHM-175 strain of hepatitis A than 25% and 40%, respectively, in any kind of than 25% and 40%, respectively, in any kind of water. The charge of glass powder was modified by polyethylenimine treatment. Concentration efficiencies of HAV in 20-L samples through adsorption to and elution from positively charged glass powder (PGPAE) were 100% for tap water, 94% for seawater, and 61% for freshwater and sewage. The presence of wild-type HAV in sewage samples could be monitored by molecular hybridization with cDNA probes after GPAE concentration. (See also W91-10612) (Author's abstract) W91-10652 W91-10658

ADSORPTION OF VIRUSES BY DIATOMA-CEOUS EARTH COATED WITH METALLIC OXIDES AND METALLIC PEROXIDES.

Florida Univ., Gainesville. Dept. of Microbiology and Cell Science.

S. R. Farrah, and D. R. Preston. Water Science and Technology WSTED4, Vol. 24, No. 2, p 235-240, 1991. 3 tab, 13 ref.

Descriptors: \*Adsorption, \*Diatomaceous earth, \*Filters, \*Oxides, \*Viruses, \*Water analysis, \*Water treatment, Aluminum, Bacteriophage, Cal-cium, Hydrogen ion concentration, Iron, Magnesi-um, Manganese, Water quality monitoring.

It is possible to modify negatively charged micro-porous filters and other solids to increase their ability to adsorb viruses at pH 7 or higher. The production of, and virus adsorption by, diatomaceous earth coated with several metallic oxides was investigated. Untreated diatomaceous earth adsorbed less than 20% of phage MS2 or polio I at pH 7. Diatomaceous earth coated with oxides of aluminum, calcium, iron, magnesium, or manga-nese adsorbed, on average, 97% of MS2 and 98% of polio 1 under the same conditions. Diatomacouse arth coated with manganes oxide adsorbed more than 99% of MS2 and polio 1 at pH 9. Diatomaceous earth coated with ferric oxide adsorbed less than 30% of MS2 and less than 4% of polio 1. Filters containing diatomaceous earth coated with magnesium peroxide adsorbed 83% to 98% of test viruses in water at pH 8.6 even after 100 L had been filtered. Filters made with solids coated with magnesium peroxide may prove useful in removing viruses from treated water or in recovering viruses from water as part of monitoring covering viruses from water as part of monitoring procedures. Coatings of magnesium peroxide are relatively stable and capable of adsorbing viruses in water even after passage of 100 L of water through 3.5 g of coated diatomaccous earth. The more rapid inactivation of bacteria than of viruses on filters. containing magnesium peroxide may filters containing magnesium peroxide may prove useful in reducing bacterial contamination of eluates of filters that are used to recover viruses from natural environments. # Identification Of Pollutants-Group 5A

DETECTION OF ROTAVIRUS IN SOUTH AF-RICAN WATERS: A COMPARISON OF A CY-TOIMMUNOLABELLING TECHNIQUE WITH COMMERCIALLY AVAILABLE IMMUNOAS-

Council for Scientific and Industrial Research, Pre-toria (South Africa). Div. of Water Technology. B. Genthe, G. K. Idema, R. Kfir, and W. O. K.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 241-244, 1991. 2 fig, 1 tab, 10 ref.

Descriptors: \*Immunoassay, \*Pollutant identifica-tion, \*Rotaviruses, \*South Africa, \*Viruses, \*Water analysis, Comparison studies, Enzymes, Freshwater, Seawater, Ultrafiltration, Wastewater.

A cytoimmunolabelling technique was compared with commercially available immunoassays for the detection of simian rotavirus SA11 and human rotavirus in various environmental samples. The rotavirus in various environmental samples. The technique is based on labelling MA104 cells with antibody conjugated with an enzyme for the detection of rotavirus. Water samples were concentrated by ultrafiltration and inoculated on trypsin-treated MA104 cells. After 18 h incubation, evidence of wirel replication was determined by impunolabell. MA 104 cells. After 18 h incubation, evicence or viral replication was determined by immunolabelling of viral antigen using antibodies tagged with horseradish peroxidase. The cytoimmunolabelling method was 100,000 more sensitive for the detection of rotavirus than commercially available enzyme-linked immunosorbent assay (ELISA) and enzyme-instea immunosoroeni assay (ELSA) and latex agglutination kits. The cytoimmunolabelling technique was also successfully detected human rotavirus in river and marine waters and wastewater effluents. The method, which is based wastewater efficients. The includy, winch is based on the detection of early viral replication, is unique for its specificity to detect infectious virus. The incidences in which no viruses were detected by the cytoimmunolabelling method but were detectthe cytoimmunolabelling method but were detected by ELISA might be attributed to the fact that ELISA and the latex agglutination methods detect viral antigen whether the viral particles are infectional methods detect the viral particles are infection. viral antigen whether the viral particles are infectious or not. Another possibility is false positive reactions using ELISA. The determination of infectivity and the increased sensitivity make the cytoimmunolabelling technique the method of choice for detecting rotavirus in environmental water samples. DIFFICULTY OF USING COLIPHAGES AS INDICATORS' AND INDEX' ORGANISMS. Tuebingen Univ. (Germany, F.R.). Hygiene Inst. M. Karst, R. Dutkiewicz, T. Hahn, and K.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 245-250, 1991. 6 fig, 12 ref.

Descriptors: \*Bacteriophage, \*Bioindicators, \*Coliphages, \*Pollutant identification, \*Viruses, \*Water analysis, \*Water quality monitoring, Detergents, Drinking water, Enteric viruses, Filtration, Flocculation, Regulations, Sample preparation,

Concentrating methods for coliphages were investigated. In experiments with seeded tap water, more T-coliphages were recovered by flocculation than by filtration. Although there was only a slight difference between flocculation and filtration in the recovery of MS2 and phi-X174 phage, recovrecovery of these phages was generally greater than that of T-phages. Filtration was slightly superior for coliphages from environmental samples. Recovery with floculation as a whole was 70% or more but fluctuated between 50% and 70% with filtration techniques. There was a major drop in recovery with flocculation and filtration when the anionic detergent Marlon A was present in concentrations of 100 mg/L or more. Nonionic detergents had of 100 mg/L or more. Nonionic detergents had little or no influence even in concentrations of 100 mg/L. For both detergents the concentration of 100 mg/L is 500 times the maximum allowed by German drinking water ordinances. Various difficulties make coliphages impractical as index organisms, or even as indicators, especially in a direct plaque assay in which half of the medium (the sample) cannot be standardized. Furthermore, coliphages are different from enteric viruses in transportation and inactivation behavior, so that colip portation and inactivation behavior, so that coli-phages may be detectable in one aquifer but not

another. It is concluded that coliphages are probably useful only as indicators in a strictly defined system. (See also W91-10612) (Doria-PTT) W91-10661

OCCURRENCE OF MALE-SPECIFIC AND SO-MATIC BACTERIOPHAGES IN POLLUTED SOUTH AFRICAN WATERS.

The isolation and preliminary characterization of some polyvalent coliphages multiplying in raw sewage in Bahrain (Persian Gulf) was determined. These polyvalent phage may be useful for the biological control of overwhelming populations of fecal coliforms found in raw sewage prior to treatment. Escherichia coli B overnight cultures and fresh two hours log-phase cultures were used for isolation and plaque assay of sewage coliphages. Enumeration of phage was carried out on E. coli By an agar overlay technique. High concentrations of coliphage were isolated during December and March, when the maximum average daytime temperature reaches 20 C. Eight coliphages capable of infecting various strains of E. coli and a few selected enterobacters were isolated. Although all polyed enterobacters were isolated. Although all poly-valent phages contained DNA, they showed variavalent phages contained DNA, they showed varia-tion in plaque size and heat sensitivity. Data clearly confirm the isolation of 8 biologically different colliphages capable of infecting various strains of E. coli and Shigella flexneri. Further studies on the genetics, physicochemical properties, and serologi-cal aspects of this problem are underway to char-acterize each of the virus isolates. Direct detection and enumeration of pathogenic bacteria, rather than indicator organisms, in aquatic environments is desirable but hindered by the difficulties of culturing and identifying specific pathogens from these environments. A method was developed for concentrating these bacteria from water samples and extracting their DNA and RNA for use as targets for pathogen-specific gene probes. The method was used to detect and enumerate Salmonella spp. in estuarine water samples. The probe binds Salmonella DNA quantitatively, making it possible to estimate relative amounts of target in each sample. Salmonella spp. were detected in samples that yielded no Salmonella spp. using ed in samples that yielded no Samiolicias spp. using culturing. Since the probe method does not require culturing the target organism, both culturable and nonculturable forms are detected. Polymerase chain reaction was also used to amplify a region of the enterotoxin gene in enterotoxigenic Escheri-chia coli and Vibrio cholerae (Itx and ctx, respec-tively). The amplified products are then identified with ctx and Itx probes, making specific, highly

sensitive detection possible. (See also W91-10612) (Author's abstract) W91-10664

DETECTION OF HEPATITIS A VIRUS AND OTHER ENTEROVIRUSES IN WASTEWATER AND SURFACE WATER SAMPLES BY GENE PROBE ASSAY

Laboratoire d'Hygiene de la Ville de Paris (France).

(France).

S. Dubrou, H. Kopecka, J. M. Lopez Pila, J. Marechal, and J. Prevot. Water Science and Technology WSTED4, Vol. 24, No. 2, p 267-272, 1991. 2 fig. 3 tab, 13 ref.

Descriptors: \*Enteroviruses, \*Gene probes, \*Nucleic acids, \*Poblitant identification, \*Public health, \*Viruses, \*Wastewater analysis, Culturing techniques, Genetics, Human diseases, Pathogens, Sample preparation, Surface water, Water analysis, Water quality monitoring.

A specific hybridization test was developed for the detection of hepatitis A virus (HAV) and other enteroviruses by using subgenomic dRNA transcripts of poliovirus type 1 (PVI) and HAV synthesized in vitro (riboprobes). Enteroviruses were specifically detected by dot blot hybridization when using PVI-derived subgenomic radiolabelled cRNA probes in environmental water samples and in the cell cultures in which the viruses were amplified. The riboprobe corresponding to the 5' noncoding sequence detected the majority of enteroviruses. HAV was specifically detected by an HAV cRNA probe corresponding to the 5' noncoding region of its genome. By this test, the limit of detection of coxsackievirus B3 and echovirus 7 of detection of coxsackievirus B5 and echovirus 7 seeded in mineral water was 1,000 to 10,000 pfu/spot. In cell cultures, positive signals were observed in the lysates of cells infected by one plaque-forming unit (pfu). Higher positive signals were obtained with a short PVI probe (nt 221-670) corresponding to the 5' noncoding region, which is a well conserved sequence among the enteroviruses, than with PVI genomic probe. Hybridization allowed a good detection of enteroviral RNAs in wastewater samples, but with a lower efficiency in surface water. In this case, amplification of viruses in the cell cultures gave significant hybridization results. It is concluded that hybridization is a relatively rapid and specific tool for screening a large of detection of coxsackievirus B5 and echovirus 7 tively rapid and specific tool for screening a large number of water samples. DETECTION OF POLIOVIRUS IN WATER BY DIRECT ISOLATION OF THE RNA AND HYBRIDIZATION WITH GENE PROBES.

Tuebingen Univ. (Germany, F.R.). Hygiene Inst. D. Tougianidou, and K. Botzenhart. Water Science and Technology WSTED4, Vol. 24, No. 2, p 273-276, 1991. 2 fig, 1 tab, 8 ref.

Descriptors: "Gene probes, "Genetics, "Nucleic acids, "Poliovirus, "Pollutant identification, "Viruses, "Water analysis, "Water quality monitoring, Adsorption, Cellulose, Enzymes, Filters, Filtration, Isolation, Public health, RNA.

A method is presented for rapid and low-cost detection of viruses in water by direct isolation of viral RNA after filtration through cylindrical cel-lulose ester filter units. Water seeded with poliovi-rus was filtered through Sterivex-OS filter units in the presence of AlCl3 to enhance viral adsorption. The filter material consisted of mixed cellulose The filter material consisted of mixed cellulose esters with a porosity of 0.22 microns. The isolation of RNA occurs in the cylindrical filter unit in the presence of RNAsse inhibitors proteinase K and sodium dodacyl sulfate (SDS); the RNA can then be detected with gene probes. The problem of limited filter capacity was overcome by filtering through 2 or more filter units. The use of prefilters is also possible, but leads to loss of virus. The cDNA probe used hybridizes mainly with politovirus types 1-3. There are some weak cross-reactions with some cossackie and echoviruses, but they can with some coxsackie and echoviruses, but they can be minimized by stringent washing conditions. The riboprobe is able to detect RNA of poliovirus types 1-3, coxsackie A virus types 7, 9, 11, and 33,

#### Group 5A-Identification Of Pollutants

and human rhinovirus type 2. For better identifica-tion of low RNA quantities, the isolated RNA can be amplified using polymerase chain reaction tech-niques. (See also W91-10612) (Doria-PTT) niques. (See W91-10666

APPLICATION OF A POLIOVIRUS CDNA PROBE FOR THE DETECTION OF ENTERO-VIRUSES IN WATER. New Hampshire Univ., Durham. Dept. of Microbi-

ology.
A. B. Margolin, M. J. Hewlett, and C. P. Gerba.

A technique is described for the detection of enter-A technique is described for the detection of enter-oviruses in water using gene probes in a dot blot assay. Policovirus cDNA probes were labeled with (P32)dCTP and (P32)dATP to a specific activity greater than 2 billion cpm/microgram DNA. The viral cDNA probe was labeled while still inserted in the plasmid vector pBR322. Autoradiograph times were compared to determine the minimum time required to optimize the sensitivity of the test. One infectious unit of poliovirus was detected from cell harvests within 48 hours using gene probes. There does not seem to be an increase in the sensitivity of the assay system by increasing the exposure time from 36 to 48 hours for detection of poliovirus. Potential false positive reactions be-tween bacterial DNA in environmental samples iween bacterial DNA in environmental samples and vector DNA were controlled by both base hydrolysis of viral RNA and enzymatic treatment of the sample. Groundwater samples were tested to determine the effectiveness of gene probes in detecting naturally occurring viruses. Results were compared to those obtained by cell culture and dot blot assay. Four of ten groundwater samples were positive by gene probes, while five were positive by cell culture. Only one sample was positive by standard cell culture techniques and negative by the dot blot assay. (See also W91-10612) (Doria-PTT) W91-10667

DETECTION OF ROTAVIRUSES IN WATER BY GENE PROBES

Arizona Univ., Tucson. Dept. of Microbiology and Immunology.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 281-284, 1991. 1 fig, 2 tab, 6 ref.

Descriptors: \*Gene probes, \*Genetics, \*Nucleic acids, \*Pollutant identification, \*Rotaviruses, \*Viruses, \*Wastewater analysis, \*Water quality monitoring, Chlorine, Culturing techniques, Drinking water, Enteroviruses, Enzymes, Proteins, RNA, Rivers, Spain, Water pollutions, \*Poteins, RNA, Rivers, RNA, RIVers,

Rotavirus-incorporated transcriptase was used to amplify rotaviral mRNA in environmental samples prior to detection by gene probes. Of sewage samprior to detection by gene probes. Of sewage samples tested, 35% were positive for rotaviruses by in vitro transcription/gene probe hybridization. Fifteen of the 20 samples tested were positive for enteroviruses by cell culture. Only 1 of 16 tap water samples was positive. The tap water contained 0.3 mg/L of free chlorine and was negative for enteroviruses by tissue culture. It was also negative for nonspecific probe binding. Nine surface water samples were tested by probe hybridization after in vitro transcription. Two samples from rivers in Spain suspected of sewage contamination were weakly positive. Both samples were negative for nonspecific binding of probe. One of these samples was also positive for enteroviruses by cell samples was also positive for enteroviruses by cell culture. It is concluded that in vitro transcription can be used as an amplification method for deteccan be used as an amplification method for detec-tion of rotaviruses by gene probes. Sephadex G-200 spun columns can be used to remove beef extract proteins while permitting in vitro amplifi-cation. A cloned copy of segment 4 of Wa rotavirus can be used to detect human rotavirus in water. Probing of positive samples with plasmid without vector can be used to detect nonspecific binding of probe. GROWTH OF CLINICAL ISOLATES OF ASTROVIRUS IN A CELL LINE AND THE PREP-ARATION OF VIRAL RNA. Sunderland Polytechnic (England). School of Biol-

ogy. A. P. Wyn-Jones, and A. J. Herring. Water Science and Technology WSTED4, Vol. 24, No. 2, p 285-290, 1991. 2 fig, 9 ref.

Descriptors: \*Astroviruses, \*Culturing techniques, \*Nucleic acids, \*Pollutant identification, \*RNA, \*Sample preparation, \*Viruses, \*Water analysis, \*Water quality monitoring, DNA, Feces, Gene

Astroviruses from three sources were processed to extract the RNA: of human origin, adapted to cell culture growth by passage in primary tissue; direct from feces; and of lamb origin, from gut epithelium scrapings. The first two of these were also com-pared in their growth on LLCMK2 and Caco-2 cell lines. Virus was successfully isolated direct cell lines. Virus was successfully isolated urrect from feces in the latter line, although it failed to grow in LLCMK2. Previously adapted virus continued to grow well in both lines. RNA was extracted from the ovine virus in a condition which permitted the production of cDNA prior to cloning, but the RNA from the human astroviruses was referently to extraction owing to its aggregamore refractory to extraction owing to its aggrega-tion with cell debris. This study demonstrated that Caco-2 cells, of intestinal epithelium origin, are capable of supporting the production of astrovirus antigen from samples that had not had prior pasantigen from samples that had not had prior pas-sage in primary cell culture. The preparation of RNA from clinical material, in this case lamb astrovirus, should facilitate the later preparation of cDNA probes, especially if astroviruses show the same extent of sequence conservation as is seen in the picornaviruses. It is concluded that, provided adequate concentration methods are available, the potential now exists for the incidence of astrovir-uses to be determined in the aquatic environment. PCR AND ENVIRONMENTAL MONITORING: THE WAY FORWARD. Lancaster Univ. (England). Inst. of Environmental

and Biological Sciences.

L. M. Alexander, and R. Morris. Water Science and Technology WSTED4, Vol. 24, No. 2, p 291-294, 1991. 6 ref.

Descriptors: \*DNA, \*Nucleic acids, \*Pollutant identification, \*RNA, \*Viruses, \*Water analysis, \*Water quality monitoring, Chemical interference, Coastal waters, Culturing techniques, Enterovir-uses, Enzymes, Gene probes, Genetics, Polymerase chain reaction, Surface water.

The polymerase chain reaction (PCR) has immeasurable potential if applied to the detection of enter-oviruses in water, as it can detect both DNA and RNA viruses. Unlike traditional tissue culture methods or molecular probes, the amplification of distinct genomic segments from different viruses can be accomplished using different oligonucleo-tides to prime PCR. This would facilitate not only group detection, such as the presence or absence of enteroviruses in a given water sample, but also the distinction between different serotypes, such as poliovirus types 1, 2, and 3. However, as is the case with any enzymatic reaction, PCR is easily inhibited by the presence of components of surface waters and probably coastal waters. While PCR is undoubtedly a powerful tool, its sensitivity is inex-tricably linked to the cleanliness, or purity, of the water concentrates from which nucleic acids are to be extracted. Until the issues of adaptability, inhi tion, infectivity, and quantification have been ad-dressed, it is unlikely that PCR can be applied reliably, on a routine basis, to the detection and monitoring of enteroviruses in environmental sam-ples. The issue of false positives and false negatives, which is a major consideration in the applica-tion of PCR to the testing of clinical samples, should continue to be given equal importance in assessing whether or not PCR is the way forward for environmental monitoring. ASSESSMENT OF METHODS FOR THE MI-CROBIOLOGICAL ANALYSIS OF SHELL-

Pretoria Univ. (South Africa). Dept. of Medical

Virology. W. O. K. Grabow, J. C. de Villiers, and N.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 413-416, 1991. 2 tab, 6 ref.

Descriptors: \*Bacterial analysis, \*Bacteriophage, \*Pollutant identification, \*Shellfish, \*Tissue analysis, \*Viruses, Agars, Coliforms, Culturing techniques, Enteric bacteria, Enzymes, Filtration, Growth media, Membrane filters, Microbiological studies, Most probable number test, Oysters, Sea mussels, Wastewater.

The efficiency of membrane filtration (MF) techniques and most probable number (MPN) tube dilution assays for the bacteriological analysis of homogenized oyster and mussel meat was comnomogenized oyster and musel meat was com-pared. Tests were done on naturally contaminated shellfish and on homogenates seeded with sewage. Digested homogenates (5% trypsin for 20 min at 37 C) were prefiltered (pore size 5 microns) and then filtered (pore size 0.45 microns) for MF counts. Undigested homogenates and dilutions were inoculated into tubes with growth medium for MDN tests. Homogenetic citis on without for MPN tests. Homogenates (with or without trypsin) were used directly in a toplayer method for the detection of coliphages. Trypsin digestion significantly reduced counts of total coliform bacteria, but not of fecal coliform bacteria, enterococci, or coliphages. Prefiltration considerably reduced counts of bacteria, and, to a lesser extent, duced counts of bacteria, and, to a lesser extent, also of coliphages. As a result, MPN tests using minerals-modified-glutamate broth yielded higher counts of coliform bacteria than MF tests using mEndo LES and mTEC agar. The latter yielded higher counts of fecal coliforms than mFC agar. In the case of entercococi, the MF procedure yielded lower counts than a spread plate test using undilower counts than a spread plate test using undi-gested homogenates. The favorable results ob-tained with spread plates in tests for enterococci suggest that spread plates may also prove superior to the MPN procedure for fecal coliforms. In this case, mTEC agar, which yielded higher average counts than mFC agar, would probably be the growth medium of choice. (See also W91-10612) (Author's abstract) W91-10695

DETOXIFICATION BY SEPHADEX LH20 OF SEAFOOD CONCENTRATES FOR ROTA-VIRUS ASSAY.

VIRUS ASSAT.

Nancy-1 Univ. (France). Faculte de Pharmacie.
C. Beril, S. Boher, and L. Schwartzbrod.

Water Science and Technology WSTED4, Vol.
24, No. 2, p 417-421, 1991. 3 tab, 9 ref.

Descriptors: \*Assay, \*Bioassay, \*Detoxification, \*Gels, \*Rotaviruses, \*Sample preservation, \*Shell-fish, \*Viruses, Culturing techniques, Filtration, Mollusks, Oysters, Sea mussels, Toxicity.

Virological analysis of seafood is often limited by the toxic effects of the mollusk concentrates on cell cultures. A detoxification method was developed based on filtration through a Sephadex LH20 gel. For oysters results show that after LH20 filtration octotoxicity decreased by a factor of 4-10 in total octotoxicity decreased by a factor of 4-10 in 55.5% of concentrates, inferior to 4 in 22% and superior to 10 in 22%. There was no significant difference in viral titre before and after filtration in 77% of cases, a significant decrease in 11% of cases, and a significant increase in 11% cases after filtration. Analysis of mussel concentrates showed that LH20 Analysis of museel concentrates showed that LH20 Sephades gel filtration reduced toxicity by a factor of 4-10 in 79% of cases, inferior to 4 in 16% and superior to 10 in 5%. The viral titre did not show any significant difference in 74% of cases. In 16%

#### Identification Of Pollutants-Group 5A

the titre obtained after detoxification was signifithe tire obtained after detoxification was signifi-cantly lower, and in 10% no rotaviruses were isolated after LH20 Sephadex gel filtration. In order to verify that LH20 Sephades filtration does not lead to a loss of viral particles, a rotavirus suspension was titrated 3 times before and after filtration on LH20 Sephadex gel. Results showed that there is no significant decrease of viral suspension titre after filtration. LH20 Sephadex gel filtration is a simple method for decreasing shellfish toxicity and improving virus recovery from these organisms. (See also W91-10612) (Doria-PTT) organisms. W91-10696

COMPARISON OF TWO METHODS FOR THE RECOVERY OF ROTAVIRUS FROM MUS-SELS AND OYSTERS. Nancy-1 Univ. (France). Faculte de Pharmacie. S. Boher, C. Beril, D. Terver, and L.

S. Boher, C. Berli, D. Terver, and D. Schwartzbrod.
Water Science and Technology WSTED4, Vol. 24, No. 2, p 423-426, 1991. 2 fig, 12 ref.

Descriptors: \*Mussels, \*Oysters, \*Pollutant identification, \*Rotaviruses, \*Shellfish, \*Viruses, Comparison studies, Extraction techniques, Flocculation, Hydrogen ion concentration, Mollusks, Seawater. Tissue analysis.

Two extraction-concentration methods for recovering rotavirus from mussels and oysters were compared. One method used was elution with 0.1 M borate-beef extract solution at pH 9 and concentration by polyethylene glyeol (PEG) 6000 double tration by polyethylene giyeoi (PEG) 6000 double precipitation. The other method was based on elution with 0.1 M glycine at pH 10 associated with organic flocculation. Mollusks were artificially contaminated by a one-hour stay in seawater seeded with rotavirus SA 11. The recovery of rotaviruses from musels depended on the procedure. With glycine-organic flocculation, the rotavirus recovery level was identical at all virus con-centrations in seawater. With the borate-beef excentrations in seaward. With the obtained for rota-tract-PEG 6000 procedure, the quantities of rota-virus recovered from mussel tissue depended on seawater contamination. When rotaviruses were less than fluorescent foci (100) FF/ml in seawater, their recovery was less efficient than that obtained their recovery was less efficient than that obtained by glycine-organic flocculation. With 100 to 320 FF rotavirus/ml seawater, the recovery is more efficient when using the borate-beef extract-PEG 6000 procedure. Oyster contamination was always made in seawater containing more than 67 FF rotavirus/ml. The borate-beef extract-PEG 6000 rotavirus/mi. The borate-beef extract-F25 door method gave significantly higher rotavirus recovery than the glycine-organic flocculation method. The borate-beef extract method provides more efficient rotavirus recovery and can be recommended for rotavirus extraction and concentration from shellfish. (See also W91-10612) (Doria-PTT) W91-10697

COMPARISON OF METHODS FOR THE ISO-LATION OF A WIDE RANGE OF VIRUSES FROM SHELLFISH.

Council for Scientific and Industrial Research, Pretoria (South Africa). Div. of Water Technology. G. K. Idema, B. W. Bateman, R. Kfir, and W. O. K. Grabow.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 427-430, 1991. 2 tab, 11 ref.

Descriptors: \*Enteroviruses, \*Pollutant identifica-tion, \*Shellfish, \*Viruses, Adsorption, Comparison studies, Desorption, Hydrogen ion concentration, Isolation techniques, Tissue analysis

Four methods were compared for the isolation of a wide range of enteric viruses from shellfish. Three of the methods (A, B, and C) were based on viral adsorption and desorption using buffers at different pH values. A fourth method (D) consisted of a single homogenization step with no pH adjust-ments. High recoveries for polio 1 were shown ments. High recoveries for polio I were shown with the first three methods, namely 81%, 79%, and 77%, respectively. Recoveries for reo I (Lang strain) and the simian rotavirus SA11 were not satisfactory using methods A-C. By contrast, method D gave high recoveries for reo and SA11 virus (31% and 68%, respectively). A modified method D generally yielded higher recoveries as indicated by a 91%, 33%, and 35% recovery for polio 1, reo, and SA11 viruses, respectively. Comparison of method A and modified method D for the detection of viruses from environmental shell-fish samples indicated that the two methods were fish samples indicated that the two methods were of equal sensitivity. The higher recoveries of reo and SA11 by method D could be due to a reduced effect of pH on adsorption and desorption compared to poliovirus, especially at low conductivity. An additional concentration step could increase the recovery and detection capabilities of the modified method even further. Method D is a very short and practical method that could be applied with ease to recover a high percentage of a wide range of viruses. (See also W91-10612) (Doria-PTT) W91-10698

PHOSPHORUS IN THE TRUCKEE RIVER BETWEEN VISTA AND PATRICK, STOREY AND WASHOE COUNTIES, NEVADA, AUGUST

Geological Survey, Carson City, NV.

Available from the US Geological Survey, Books and Open-File Reports Section, Federal Center, Box 25425, Denver, CO 80225-0425. Water-Re-sources Investigations Report 89-4175, 1990. 33p, 11 fig, 6 tab, 19 ref.

Descriptors: \*Lake Tahoe Basin, \*Monitoring, \*Nevada, \*Phosphorus, \*Sampling, \*Truckee River, \*Water analysis, \*Water sampling, Dissolved oxygen, Dissolved solids, Pyramid Lake, Reno, Sewage disposal, Sparks, Storey County, Streamflow, Trace elements, Traveltime, Washoe County, Water quality data, Water quantity.

During calibration of a numerical water quality model of the Truckee River below Reno, Nevada, the modeling results showed an undocumented accretion of phosphorus between Lockwood and Patrick at streamflows of about 300 cu ft/sec. An examination of available historical data tended to examination of available instorical data reflued to support the observed increase. In August 1984, at a streamflow of about 300 cu f/sec, a diel sampling program was undertaken at four stations along a 7.3-mile reach of the river to determine if the undocumented input of phosphorus was real, or was due to errors associated with water quality sampling procedures, or the river's traveltime, or both. Water samples were collected using the equal-discharge-increment method across the stream, for the analysis of phosphorus, chloride, sulfate, and arsenic. On-site measurements included specific conductance, dissolved oxygen, water temperature, and pH. All water quality data were temperature, and pH. All water quality data were collected every 2 hours and instantaneous streamflow was measured about every 3 hours at each station. The results of field work and a thorough analysis of past sampling programs in the Truckee River suggest that the apparent increase in phosphorus between Lockwood and Patrick was most likely the result of sampling protocol in association with the river's time of travel, compounded by fluctuating phosphorus loads from an upstream wastewater treatment plant near Reno during periods of moderate streamflow. During high streamflow conditions, the increase may also have been the result of the resuspension of particulate phosphorus. (Author's abstract)

CONE PENETROMETER TESTS AND HY-DROPUNCH SAMPLING: A SCREENING TECHNIQUE FOR PLUME DEFINITION.

EMCON Associates, San Jose, CA. M. Smolley, and J. C. Kappmeyer. Ground Water Monitoring Review GWMRDU, Vol. 11, No. 2, p 101-106, Spring 1991. 4 fig, 2 tab,

Descriptors: \*Groundwater pollution, \*Monitoring, \*Path of pollutants, \*Plumes, \*Volatile organic compounds, Aquifer characteristics, Cone penetrometer test, Cost analysis, Data acquisition, Field tests, HydroPunch sampling, Monitoring wells, Sampling, Wall data Sampling, Well data.

Cone penetrometer tests and HydroPunch sampling were used to define the extent of volatile organic compounds in groundwater. The investigaorganic compounds in groundwater. In envestiga-tion indicated that the combination of these tech-niques is effective for obtaining groundwater sam-ples for preliminary plume definition. HydroPunch samples can be collected in unconsolidated sediments and the analytical results obtained from these samples are comparable to those obtained from adjacent monitoring wells. This sampling method is a rapid and cost-effective screening techinque for characterizing the extent of contaminant plumes in soft sediment environments. Use of this screening technique allowed monitoring wells to be located at the plume boundary, thereby reduc-ing the number of wells installed and the overall cost of the plume definition program. FIELD SAMPLING OF RESIDUAL AVIATION GASOLINE IN SANDY SOIL.

Massachusetts Univ., Amherst, Dept. of Civil En-

D. W. Ostendorf, L. E. Leach, E. S. Hinlein, and

Ground Water Monitoring Review GWMRDU, Vol. 11, No. 2, p 107-120, Spring 1991. 6 fig. 10 tab, 17 ref, append. U. S. Environmental Protec-tion Agency Contract CR 816821.

Descriptors: \*Field tests, \*Gasoline, \*Monitoring, \*Pollutant identification, \*Sampling, \*Soil analysis, \*Soil contamination, Analytical methods, Comparison studies, Cores, Gas chromatography, Precision, Sand, Soil profiles.

Two complementary field sampling methods were evaluated for the determination of residual aviation gasoline content in the contaminated capillary fringe of a fine, uniform, sandy soil. The first method featured field extrusion of core barrels into pint-size Mason jars, while the second consisted of laboratory partitioning of intact stainless steel core sleeves. The barrel extrusion procedure involved jar headspace sampling in a nitrogen-filled glove box. Soil samples removed from the Mason jars (in the field) and sleeve segments (in the laboratory) were subjected to methylene chloride extraction and gas chromatographic analysis to compare their aviation gasoline content. The barrel extrusion sampling method yielded a vertical profile with 0.10m resolution over an essentially continuous 0.10m resolution over an essentially continuous 5.0m interval from the ground surface to the water table. The sleeve segment alternative yielded a more resolved 0.03m vertical profile over a shorter 0.8m interval through the capillary fringe. The two methods delivered precise estimates of the verticalmethods delivered precise estimates of the vertical-ply integrated mass of aviation gasoline at a given horizontal location, and a consistent view of the vertical profile as well. The maximum peak was resolved by the core sleeve data, but was partially obscured by the barrel extrusion observations, so that replicate barrels or a half-pint Mason jar size should be considered for data supporting vertical transport analyses in the absence of sleeve parti-tions. Groundwater contamination by non-aqueous phase liquid (NAPL) chemicals is a serious concern at many industrial facilities and waste disposal sites. In order to develop rational and cost-effective plans for remediation of soil and groundwater conplans for remediation of soil and groundwater con-tamination at such sites, it is essential to determine if NAPL chemicals are present in the subsurface and delineate the zones of NAPL contamination. A method has been developed to allow investiga-tors of chemical spill and waste disposal sites to address whether soil chemical analyses indicate the presence of residual NAPL in the subsurface. The method requires information on the soil gathered method requires information on the soil gathered in groundwater contamination studies: total chemiin groundwater contamination studies: total chemical concentrations, moisture content, porosity, sorption parameters for the chemicals of interest, and physical and chemical properties of the chemicals of interest. Conclusions regarding the presence of NAPL in soil samples are most reliable for cases where significant residual NAPL is present; the pore water-soil partition coefficients can be measured for the compounds of interest; and for single component or multicomponent NAPL for which the effective solubility of the components can be measured. The determination of the presence of NAPL is less reliable when parameters such as sorption coefficients and effective solubility must be estimated. However, at the present time calculations. be estimated. However, at the present time calcula-tions such as this provide the only method for the determination of residual NAPL in soil samples until laboratory analysis methods are developed which can confirm the presence of low levels of NAPL contamination directly. SPECTROPHOTOMETRIC DETERMINATION OF NITRITE IN POLLUTED WATERS USING 3-NITROANILINE.

Aligarh Muslim Univ. (India). Chemistry Section. H. P. S. Rathore, and S. K. Tiwari. Analytica Chimica Acta ACACAM, Vol. 242, No. 2, p 225-228, February 1991. 3 tab, 23 ref.

Descriptors: \*Analytical methods, \*Chemical analysis, \*Nitrites, \*Pollutant identification, \*Spectrophotometry, \*Water analysis, Chemical reactions, Chemical reagents, Hydrogen ion concentration, Interference, Laboratory methods, Reproducibility

Nitrite reacts with 3-nitroaniline in the presence of Nitrite reacts with 3-nitroaniline in the presence of hydrochloric acid to form a diazonium cation, which is subsequently coupled with N-(1-naphthyl)ethylenediammonium chloride to form a stable purple azo dye. The method is suitable for the determination of 0.01-0.80 microgram/ml nitrite. The reactions are very fast and require no control of temperature. The observed molar absorptivity and Sandell's sensitivity of the azo dye were 49.000 L/mol/cm and 0.00094 micrograms/ sq cm, respectively. The method is free from most interferences and has been applied successfully to polluted river water. The rapidity, simplicity, reroducibility, freedom from htt fefects, temperareducibility, freedom from https://doi.org/10.1001/j.j.j. producibility, freedom from pH effects, tempera-ture independence and high tolerance limits for a large number of foreign ions are significant advan-tages of this method. Descriptors: \*Analytical methods, \*Chemical analysis, \*Nitrates, \*Nitrites, \*Pollutant identification, \*Spectrophotometry, \*Water analysis, \*Water pollution, Chemistry of precipitation, Laboratory methods, Measuring instruments, Rain, Ultraviolet radiation, Wastewater analysis.

A rapid and accurate method for the direct simulis ultraviolet spectrophotometric determina-

tion of nitrate and nitrite in environmental pollution to intrate and intrite in environmental point-tion studies is proposed based on the CPA matrix method (C=PA where C is the matrix of the standard mixtures, A is the absorbance matrix and P is the matrix representing the proportionality between C and A). The analytical wavelengths and the various parameters affecting the determination of nitrate and nitrite were investigated and applied or mirate and mirate were investigated and applied to the measurement of these compounds in rainwater and wastewater without preliminary separation. Compared with conventional methods for nitrite and nitrate determination, the proposed method offers greater convenience, and higher sensitivity and sampling frequency. (Medina-PTT) sitivity and sampling frequency. (Medina-PTT)

In Germany, Stage 2 of the Chemicals Act requires a long-term fish test which must also include re-production. An early life stage (ELS) test was conducted with the zebrafish and 3,4-dichloroaniline (3,4-DCA) in eight laboratories. Based on the results from all eight laboratories, an LOEC (laboresults from all engin hoovaries, an Doc (hoovarietory-determined observed effect concentrations) of 200 micrograms 3,4-DCA/liter applies for the early life stages of the zebrafish. Effects observed were reduction of the survival rate and malformations. If the 100 microgram/liter concentration ad-ditionally tested by one laboratory is included in the assessment, an LOEC of 100 micrograms 3,4the assessment, an LOEC of 100 micrograms 3,4-DCA/liter is obtained for the survival rate and increase in length. The NOEC (no-observed effect concentrations) is 20 micrograms/liter. The present results of a comparative laboratory study with the zebrafish show that a 42-day ELS test can be conducted with this species of fish, and can afford meaningful results. Descriptors: \*Bioassay, \*Hazard assessment, \*Risk assessment, \*Toxicity, \*Toxicology, Acute toxicity, Algae, Aquatic life, Chronic toxicity, Comparison studies, Daphnia, Mathematical models.

In the future, extrapolation procedures become more and more important for the effect assessment of compounds in aquatic systems. For achieving a reliable method these extrapolation procedures have to be evaluated thoroughly. As a first step three extrapolation procedures were com-pared by means of two sets of data consisting of (semi)chronic and acute toxicity test results of 11 (semichronic and acute toxicity test results of 11 aquatic species and 8 compounds. Because of its statistical basis the extrapolation procedure of Van Straalen and Denneman, which uses the log-logistic distribution, was preferred over the procedures of the EPA and Stephen et al, which uses the triangular distribution. The results of the calculations of the content of the calculations of the content of the calculations of the content of the calculations of the c triangular distribution. The results of the calcularions showed that lower numbers of toxicity data increase the chance of underestimating the risk of a compound. Therefore it is proposed to extend the Organization for Economic Cooperation and Development guidelines for algae, Daphnia, and fish with chronic (aquatic) toxicity tests for more species of different taxonomic groups. Using a flow-through biotest exposure system, cod eggs, larvae and juveniles were exposed to the water-soluble fraction (WSF) of North Sea (Stratfeggs, inrake and juvenines were exposed to the water-soluble fraction (WSF) of North Sea (Stratf-jord B) crude oil at concentrations ranging from 40-300 micrograms/L (ppb) for 1-6 weeks. The WSF was analyzed by gas chromatography/mass spectrometry (GC/MS), and was shown to be dominated by low-aromatic compounds such as benzenes, toluene and xylenes (80-90%). Cytochrome P450IA1 levels were measured by immunochemical techniques in 10,000 X g supernatants of whole larvae or juvenile gill homogenates, and in juvenile liver microsomal fractions. With rabbit anti-cod P450IA1 IgA as primary antibody in an indirect enzyme-linked immunosorbent assay (ELISA), a clear induction response was observed in the exposed groups of both larvae and juveniles. The response was dose-dependent, and recovery in clean sea-water resulted in normalization of the induced P450IA1 levels. In larvae exposed during induced P450AI1 levels. In larvae exposed during the egg stage, the induction process seemed re-stricted until the time of hatching. In juvenile cod, the response was observed in the gill in addition to the liver. The study demonstrates the usefulness of the cytochrome P450AII ELISA in detecting sublethal biological effects of pollutants in

The concentrations of Pb and Se in the limpet Patella vulgata, the bivalve Mytilus minimus, and the amphipod Hyale prevosti at 6 intertidal locations off the Alexandria coast were investigated. The sampled stations were under the direct stress of untreated agricultural/industrial or sewage discharge. Generally, the capacity of Mytilus in accumulating Pb was higher than Patella and Hyale while for Se the sequence was Patella > Hyale > Mytilus. The feeding habit for each species influences the Pb and Se content of tissue and thus the presence of Pb in both soluble and particulate forms in water render it more available to filter feeding bivalves. The heterogeneity in shell measurements for Patella and Mytilus at different sampling, sites masks the appearance of a statistically pling sites masks the appearance of a statistically significant relation between shell measurements and Pb and Se content. The simple linear log regression between dry weight and concentratio indicated a decrease in concentration with increase indicated a decrease in concentration with increas-ing animal weight, which is partially attributed to the higher metabolic rate of smaller organisms. In the absence of M. edulis in Alexandria coastal waters, M. minimus will serve as a bioindicator for Pb and Se enrichment; Patella and Hyale should also be considered. (Sand-PTT)

DETERMINATION OF CHLORINATED PHENOXY ACID AND ESTER HERBICIDES IN SOIL AND WATER BY LIQUID CHROMA-TOGRAPHY PARTICLE BEAM MASS SPECTROMETRY AND ULTRAVIOLET ABSORPTION SPECTROPHOTOMETRY.

Eight chlorinated phenoxy acid and three ester Eight chlorinated phenoxy acid and three ester herbicides are determined in soil and water by liquid chromatography with UV absorption for quantitation and particle beam mass spectrometry for confirmation. Chromatography using a C-18 reversed-phase column, 22 cm x 2.1 mm, water with methanol or acetonitile and acetic acid mobile phase, 0.25 mL/min flow, with UV detection (230 nm) gives quantitation limits of 12-80 ng in 10 microlitet piecetd volume (corresponding to tion (230 nm) gives quantitation limits of 12-90 ng in 10 microliter injected volume (corresponding to 4.8-32 ppb in 125 mL of water and 20-133 ppb in 30 g of soil and 500 microliter of final extract volume) with four-point calibration (R > 0.99). Full scan electron ionization particle beam mass spectra are given for chlorinated phenoxy acids at 1.25 microgram each on-column, showing molecular and phenoxy (base) ions. Both acids and esters are efficiently and cleanly extracted from soil and water with ethyl acetate, and the esters are base hydrolyzed before analysis. The average recovery of eight carboxylic acids spiked into water at 33.3, 1.0, and 0.1 ppm and spiked into soil at 33.3 and 1.0

ppm is 78% (average standard deviation 4.2%). The average recovery and ester hydrolysis efficiency for the three esters 2,4-D mixed isobutyl, 2,4,5-T butoxyethanol ether, and 2,4-DB isobutyl spiked at the same levels in soil and water is 88% (average standard deviation 10%). Descriptors: \*Analytical methods, \*Arsenic compounds, \*Chemical analysis, \*Chromatography, \*Pollutant identification, \*Separation techniques, \*Water analysis, Chelation, Gas chromatography, Heavy metals, Hydrogen ion concentration, Quantitative analysis, Thermal properties, Volatility.

Selective chelation followed by chromatographic Selective chelation followed by chromatographic separation is one method of analyzing arsenic species. The low volatility and thermal instability of arsenic species of diethyldithiocarbamate (DDC) make it difficult for quantification. Substitution of fluorine for hydrogen in DDC, as in the case of sodium bis(trifluoroethyl)dithiocarbamate (FDDC), can generally enhance the volatility and thermal stability of the resulting metal chelates. An inventibility and the case of thermal stability of the resulting metal chelates. An investigation on the characterization and GC separation of As and other relevant metal-FDDC complexes and the potential applications of this method to arsenic speciation studies was conducted. The results of differential scanning calorimetry and thermal gravimetric analysis clearly demonstrated the greater thermal stability and volatility displayed by As(FDDC)3 relative to the analogous As(DDC)3. Arsenate in aqueous solutions can be quantitatively extracted with Na-FDDC into chlorform in the pH range 2-6 according to the exquantitatively exhausted with NaT-DD- into clino-roform in the pH range 2-6 according to the ex-periments performed. pH 3 was chosen as the standard condition for extracting As(FDDC)3 in the experiments. At this pH, other metal-FDDC complexes, including those of Zn, Ni, Hg, Pb, and Bi, can also be quantitatively extracted. The method was applied to arsenic speciation in a dep well water sample collected from the 'black-foot disease' area in southwest Taiwan. The results disease' area in southwest Taiwan. The results agree with those determined by the solvent extraction and neutron activation analysis method described in previous papers. (Agostine-PTT) W91-10894

SENSITIVE HIGH-PERFORMANCE LIQUID CHROMATOGRAPHIC ANALYSIS FOR TOXICOLOGICAL STUDIES WITH CARBARYL.

Virginia-Maryland Regional Coll. of Veterinary Medicine, Blacksburg, VA. Dept. of Biomedical

J. R. Strait, G. C. Thornwall, and M. Ehrich. Journal of Agricultural and Food Chemistry JAFCAU, Vol. 39, No. 4, p 710-713, April 1991. 4 fig, 1 tab, 12 ref.

Descriptors: \*Analytical methods, \*Carbaryl, \*Detection limits, \*High performance liquid chromatography, \*Pesticides, \*Pollutant identification, \*Toxicology, Carbamate pesticides, Chromatography, Degradation products, Liquid chromatography, Metabolites, Separation techniques, Water.

Chromatographic techniques are currently used for detection of carbaryl. A simple extraction followed by HPLC analysis on a highly efficient 3 micrometer column was developed that increased sensitivity for detection of carbaryl and metabolites to the picomole range. Carbaryl and its degradation products could be detected in water and serum at levels as low as 0.5 ng/mL ( or 5% full scale responses at 0.005 aufs) by hPLC analysis using a 3 micrometer C-18 Ultrasphere column on a Beckman HPLC System. Preparation included a single extraction with methanol after application of samples to 1.0 mL of C18 solid-phase extraction columns. Advantages of this method include high

sensitivity, analysis time of 10 min after a single extraction, and high recovery. Sensitivity was maintained whether the carbaryl or its degradation products or metabolites were provided in water or in serum. This HPLC method could be useful for toxicological studies in which detection of low concentrations of carbaryl were needed. (Author's abstract) W91-10920

METHOD FOR INSTALLING MINIATURE MULTILEVEL SAMPLING WELLS.
Wisconsin Univ.-Madison. Dept. of Soil Science.
W. Stites, and L. W. Chambers. Ground Water GRWAAP, Vol. 29, No. 3, p 430-432, May/June 1991. 1 fig, 1 tab, 7 ref.

Descriptors: \*Field tests, \*Shallow wells, \*Water sampling, \*Well construction, Drilling samples, Groundwater, Groundwater quality, On-site tests,

Groundwater tracer test studies or contamination studies frequently require the removal of small quantities of water from specific depths. However, the methods previously described all require a large borehole drilled by a hollow stem auger or casing driven by a cable tool, which requires access for trucks or heavy machinery. A method has been developed to install miniature multilevel groundwater sampling wells in shallow, unconsolidated aquifers at sites without truck access. A small hole is created by driving a steel pipe into the ground, serving as a temporary casing into which a bundle of flexible polyethylene tubing is inserted. The pipe is then withdrawn, leaving only the tubing (and a disposable metal point) in the ground. An advantage of these wells over the traditional bundle-type multilevels is that this type of installation causes minimal aquifer disturbance. Groundwater tracer test studies or contamination traditional bundle-type mutitievels is trait instype of installation causes minimal aquifer disturbance. Thus, miniature multilevels can be installed while a tracer test is in progress. Furthermore, only hand tools are needed in the field, and equipment and materials are easily obtained and inexpensive. The time required for installation is comparable to other methods. (Fish-PTT)

Jodhpur usually experiences shortages of water. Many industries have moved into the region. The effluents released by the factories are toxic and potentially harmful. The waste water flows in two open drains and spreads over the land outside the city. The concentration of some toxic metal ions in city. The concentration of some toxic metal ions in the industrial waste water and fly ash from power generation plant in Jodhpur has been estimated from differential pulse polarography for zinc, and differential pulse anodic stripping voltammetry for lead, cadmium and copper. Results indicate that he concentration of lead in both cases is high. The industrial waste is toxic, and contamination of the surrounding land by lead is possible. (See also W91-11066) (Brunone-PTT)

Geonets have become a popular component of leak detection systems at surface impoundments, waste piles, landfills and heap leach systems. They pro-vide a reasonable alternative to gravel drainage designs which become costly when large quantities of leachate are anticipated. This paper examines the potential increase in in-plane flow by placing two layers of geonet materials atop one another. The increase in flow was measured for three differtwo layers of geonet materials atop one another. The increase in flow was measured for three different cross sections: geomembrane overlain double geonets overlain by geomembrane overlain by double geonets overlain by geotextile and sand; and, geomembrane overlain by geotextile and sand; and, geomembrane overlain by geotextile and clay. The effect of soil intrusion was studied on the applicable cross sections. Flow rate comparisons of the double geonet situation with a single geonet were made when used between two geomembranes and found that the normal pressure was critical in that flows were double at low pressures, but much less at high pressures. The normal compression test results gave insight into this behavior. At values of normal pressure > 10,000 lb/sq ft the upper and lower geonets reorient themselves and fold into one another resulting in only a modest improvement in a single geonet; s flow capability. The real benefit of the double geonet concept, however, was found to be when a geotextile with soil above it is used. With a single geonet, intrusion of the geotextile by the soil significantly decreases its flow capability. With the double geonet, the intrusion only occurs in the upper geonet, leaving the lower geonet completely available for flow. Effiflow capability. With the double geonet, the intrusion only occurs in the upper geonet, leaving the lower geonet completely available for flow. Efficiencies of the double geonet over the single geonet are an impressive 200 to 460 percent. This occurs at all normal pressure levels, although the higher efficiencies are at the lower normal pressure. Clearly, the double geonet scheme for increased geonet flow rate capability is a valid and creased geonet flow rate capability is a valid and worthwhile concept as long as the geonets do not reorient themselves and fold into one another. NEW DEVELOPMENTS IN SAMPLING SLUDGE TREATED SOILS. Water Research Centre, Medmenham (England).

Medmenham Lab Medmenham Lab.
J. E. Hall, and T. R. E. Thompson.
IN: Sewage Sludge Treatment and Use: New Developments, Technological Aspects and Environmental Effects. Elsevier Science Publishing Co., New York. 1989. p 504-507. 2 fig, 3 ref.

Descriptors: \*Europe, \*Heavy metals, \*Sludge disposal, \*Sludge utilization, \*Soil sampling, \*Wastewater treatment, Administrative regulations, Soil profiles, Water quality monitoring.

The European Community (EC) directive on the use of sludge on agricultural land requires member states to sample soils to a depth of 25 cm to states to sample soils to a depth of 25 cm to monitor heavy metal concentrations. Problems in-volved with this sampling include metal distribu-tion in the soil profile, soil sampling errors, the present inadequacy of mechanical soil samplers, and the difficulties in providing baseline data for this monitoring program. Many member states have to implement or change soil monitoring strat-egies. (See also W91-11115) (Brunone-PTT) W91-11158

CHEMICAL PROPERTIES OF SEWAGE SLUDGES PRODUCED IN THE VALENCIAN AREA (SPAIN).

Instituto Valenciano de Investigaciones Agrarias,

Instituto Valenciano de Investigaciones Agrarias, Valencia (Spain).

J. Roca, F. Pomares, and F. Tarazona.

IN: Sewage Sludge Treatment and Use: New Developments, Technological Aspects and Environmental Effects. Elsevier Science Publishing Co., New York. 1989. p 508-516. 6 tab, 6 ref.

Descriptors: \*Agriculture, \*Fertilizers, \*Heavy metals, \*Pollutant identification, \*Sludge disposal, \*Sludge utilization, \*Soil amendments, \*Spain, \*Wastewater treatment, Chemical properties, Chromium, Copper, Lead, Regulations, Soil chemistry, Soil contamination, Urban planning, Zinc.

The chemical characterization of sewage sludges used in agriculture as either as fertilizer or as a soil amendment is important in order to determine: amendment is important in order to determine: their suitability as agricultural soils, and the mini-mum concentrations needed for plant nutrition (to avoid eutrophication of lakes and rivers). Sewage sludge from sixteen municipal wastewater treat-ment plants located in the Valencian Region of ment plants located in the Valencian Region of Spain were analyzed periodically to verify suitability for agricultural use. The parameters studied included organic matter, fertilizer elements, salinity and heavy metals. The results obtained showed that most of the sewage sludges produced in the region are adequate for agricultural soils; however, in four out of sixteen sewage sludges the heavy metal contents of zinc, lead, copper, and chromium exceeded the Commission of European Communities (CEC) guidelines. The determination of the source of heavy metals which are polluting the sewage sludges and the prevention of their distribution into urban sewerage systems will allow a greater amount of sludge to be used for agriculture. USE OF 2,2-DIMETHOXYPROPANE FOR THE DIRECT GAS CHROMATOGRAPHIC-MASS SPECTROMETRIC DETERMINATION OF SOME ORGANIC COMPOUNDS IN WATER. Consiglio Nazionale delle Ricerche, Padua (Italy). Servizio di Sicurezza del Lavoro e Protezione

A. Sturaro, L. Doretti, and G. Parvoli. Analytica Chimica Acta ACACAM, Vol. 244, No. 1, p 9-13, March 1991. 1 fig, 3 tab, 8 ref.

Descriptors: \*Chemical analysis, \*Dimethoxypropane, \*Gas chromatography, \*Mass spectrometry, \*Organic compounds, \*Organic pesticides, \*Pollutant identification, \*Sample preparation, \*Water analysis, Analytical methods, Chemical reactions, Detection limits, Organic pollutants, Separation techniques.

The well known reaction between 2.2-dimethoxypropane (the dimethyl ketal of acetone) and water allows for the conversion of an aqueous into an organic solution ready to be injected directly into a

gas chromatographic-mass spectrometric (GC-MS) system. Only time, temperature and water/ketal ratio were the only parameters among those studratio were the only parameters among those studied which influence the equilibrium reaction. A temperature increase leads to a higher acetone conversion because the reaction is endothermic. Temperatures higher than 30 C cause negligible variations in the amount of acetone in the final mixture. Independently of the water/ketal ratio, the reaction reaches the equilibrium steady state after a short time (15 min) at the optimum temperature (30 C). If the amount of ketal in the water/ketal ratio is increased, there is a higher yield, but an excessively dilute sample is obtained. The reaction environment is not suitable for all compounds: acids, esters, alcohols, amines, ketones, and phenols tion environment is not suitable for all compounds: acids, esters, alcohols, amines, ketones, and phenols may react with methanol, acetone and ketal owing to Amberlyst being present as catalyst. This method is proposed for the GC-MS analysis of aqueous solutions containing hydrocarbons, halogenated hydrocarbons and ethers. Dichlobenil, chloroneb, gamma-hexachlorocyclohexane, chlorothalonil, fluorodifen, and 1,2-benzanthracene pesticide concentrations in water were determined using the present method. The detection limits for the pesticides examined were 0.15-0.70 mg/L, corresponding to an absolute amount of 20-90 picograms obtained with signal-to-noise ratio of 3 for the scanned peaks. (Geiger-PTT) the scanned peaks. (Geiger-PTT) W91-11245

ORGANOTIN STABILITY DURING STORAGE OF MARINE WATERS AND SEDIMENTS.

Bordeaux-1 Univ., Talence (France). Lab. de Photophysique et Photochimie Moleculaire. P. Quevauviller, and O. F. X. Donard.

Fresenius Zeitschrift fuer Analytische Chemie ZACFAU, Vol. 339, No. 1, p 6-14, January 1991. 8 fig, 8 tab, 21 ref.

Descriptors: \*Antifoulants, \*Marine sediments, \*Organotin compounds, \*Pollutant identification, \*Sample preservation, Atomic absorption spectrophotometry, Gas chromatography, Monobutyltin, Sample preparation, Seawater, Temperature, Tributyltin.

The stability, over 4 months, of organotin com Ine stability, over 4 months, of organotin compounds in seawater and sediments was studied in relation to sample preservation efficiency for later gas chromatography/atomic absorption spectrophotometry. Storage of filtered natural seawater in the dark, at pH 2, in pyrex glass bottles, is suitable to preserve the stability of tributyltin over 4 months both at 20-25 C and 4 C. The other butyltin compounds (mono-and di-butyltin) are stable at 4 C but display some losses at 25 C. A poor recovery C but display some losses at 25 C. A poor recovery of butyltins in turbid water hampered the assessment of the stability on a quantitative basis; however, it could be demonstrated on a qualitative basis that butyltin stability is uneasily achieved in water samples with high suspended matter. Wet storage and freezing preserved the tributyltin stability in sediments, as well as oven-drying (at 50 C), freeze-drying and air-drying. Mono-and di-butyltin were generally subject to changes during the storage of sediments using the different methods. (Author's abstract) W91-11255

CONTINUOUS FLOW THIN-LAYER HEAD-SPACE (TLHS) ANALYSIS. I. CONDUCTOME-TRIC DETERMINATION OF VOLATILE OR-GANIC HALOGENS (VOX) IN TAP WATER. Gdansk Technical Univ. (Poland). Inst. of Inorganic Chemistry, Technology and Corrosion. E. Kozlowski, E. Sienkowska-Zyskowska, and T.

#### Identification Of Pollutants-Group 5A

Descriptors: \*Conductivity, \*Halogenated organic compounds, \*Laboratory methods, \*Pollutant identification, \*Volatile organic compounds, \*Water analysis, \*Water quality management, Chemical analysis, Drinking water, Gas chromatography, Halogens, Mineralization, Organic compounds, Separation techniques, Sulfur, Water quality

A new method of continuous determination of A new method of continuous determination of volatile organohalogens in water is presented which is based on the thin layer headspace (TLHS) technique. Volatile analytes are isolated from the aqueous phase in a thermostatted spiral tube (TLHS column) where the sample flows in a form of a thin film countercurrently to a stream of purified air. The isolated compounds are mineralized in an empty quartz tube at 900 C, and the mineralization products are washed with triple distilled water. The conductivity of the wash solution tilled water. The conductivity of the wash solution is proportional to the VOX content. The detection is proportional to the VOX content. The detection limit is on the order of a few parts per billion. The effect of the possible interference by ammonia can be effectively removed by an ion exchange column. The effect of sulfur can be eliminated by an application of a substance binding sulfur oxides an application of a substance binding sulfur oxides and being inert toward hydrogen halides such as magnesium oxide. The method was applied to the continuous determination of organohalides in tap water. At a 95% confidence level, the relative error of the method did not exceed 6%. (Author's

A high performance liquid chromatogrpahy electrochemical method is proposed for the determination of phenol, alkylphenols, hydroxyphenols and chlorophenols. With the application of programmed flow-rate variation good resolution within short analysis times could be reached; the eluent is usable for several runs. An electrochemical dual detector provides detection limits ranging cal dual-detector provides detection limits ranging cal dual-detector provides detection limits ranging from 55 picograms for hydroquinone to 19 nano-grams for pentachlorophenol (injection volume 20 microliters). The dual mode is used to increase selectivity and sensitivity. The method was suc-cessfully applied to the direct determination of phenols in waste and river water. Phenol concentrations in wastewater from a coal manufacturing plant ranged from 0.72 to 9.64 mg/L and in Pleisse River water from 13 to 368 micrograms/L. (Author's abstract)

A joint U. S. Environmental Protection Agency/ Association of Official Analytical Chemists (AOAC) Interlaboratory method validation study was conducted on EPA Method 507, Determina-

tion of Nitrogen-and Phosphorus-Containing Pesticides in Finished Drinking Water by Gas Chromatography with a Nitrogen-Phosphorus Detector, to tography with a Nitrogen-Phosphorus Detector, to determine the mean recovery and precision for analyses of 45 nitrogen-or phosphorus-containing pesticides in reagent water and finished drinking waters. The study design was based on Youden's nonreplicate plan for collaborative tests of analyti-cal methods. The waters were spiked with 45 nitrogen-or phosphorus-containing pesticides at 6 concentration levels, prepared as 3 Youden pairs. Ten volunteer laboratories extracted the spiked test waters with methylene chloride, performed a solvent exchange with methyl tert-butyl ether, and analyzed an aliquot of each extract by gas chromaanalyzed an aliquot of each extract by gas chroma-tography using a nitrogen-phosphorus detector. Results were analyzed using an EPA computer program, which measured recovery and precision for each of the 45 pesticides and compared the performance of the method between water types. Method 507 was judged acceptable for all analytes section 307 was juuged acceptable for all analytes tested except merphos, which thermally decomposed in the injection port of the gas chromatograph. Five compounds (carboxin, disulfoton, metolaclor, pronamide, and simazine) exhibited statistically significant matrix effects for the finished drinking water. The method has been adopted drinking water. The method has been adopted official first action by AOAC. (Author's abstract) W91-11259

DIRECT AQUEOUS INJECTION-LIQUID CHROMATOGRAPHY WITH POST-COLUMN DERIVATIZATION FOR DETERMINATION OF N-METHYLCARBAMOYLOXIMES AND N-METHYLCARBAMATES DRINKING WATER: IN FINISHED COLLABORATIVE DRINKING

An Interlaboratory method validation study was conducted on EPA Method 531.1, Measurement of N-Methylcarbamoyl-oximes and N-Methylcarbamoyl-oximes and N-Methylcarbamates in Water by Direct Aqueous Injection high performance liquid chromatography (HPLC) with Post Column Derivatization, to determine the precision and mean recovery for determination of 10 carbamate pesticide compounds in reagent water and in finished drinking waters. The study design was based on Youden's nonreplicate plan for collaborative tests of analytical methods. The waters were spiked with 10 carbamate pesticides at 6 were spiked with 10 carbamate pesticides at 6 concentration levels, as 3 Youden pairs. Eight labconcentration levels, as 3 Youden pairs. Eight laboratories analyzed the samples by direct aqueous injection, with separation by reverse-phase liquid chromatography and post-column hydrolysis of the carbamates and carbamoyloximes to methylamine, followed by reaction of the methylamine with ortho-phthalaldehyde and 2-mercaptoethanol using fluorescence detection. Results were analyzed using an EPA computer program, which measured precision and recovery for each of the locomounds and compared the performance of the measured precision and recovery for each of the 10 compounds and compared the performance of the method between water types. The method was acceptable for all analytes tested. After removal of a nonrepresentative data set for aldicarb sulfoxide, no matrix effects were observed; the statistics for the pooled drinking waters were not significantly different from the statistics for the reagent waters. The method has been adopted official first action by the Association of Official Analytical Chemists. (Author's abstract) (Author's abstract) W91-11260

LIQUID CHROMATOGRAPHIC DETERMINA-TION OF GLYPHOSATE AND AMINOMETH-YLPHOSPHONIC ACID (AMPA) IN ENVI-RONMENTAL WATER: COLLABORATIVE STUDY.

Monsanto Agricultural Co., St. Louis, MO. M. E. Oppenhuizen, and J. E. Cowell.

Journal - Association of Official Analytical Chemists JANCA2, Vol. 74, No. 2, p 317-323, March/April 1991. 4 fig, 3 tab, 11 ref.

Descriptors: \*Glyphosate, \*Herbicides, \*Liquid chromatography, \*Pollutant identification, \*Water analysis, Detection limits, Laboratory methods,

A new method for determination of glyphosate and amino-methylphosphonic acid (AMPA) residues in environmental water was collaboratively studied by 6 laboratories. The method is simpler and shorter than previous methods. A filtered volume of water is evaporated to dryness and the residue is dissolved in a buffered EDTA solution. residue is dissolved in a bullered EDTA solution. Glyphosate and AMPA are determined by liquid chromatography with postcolumn reaction detection. The method was validated over the range 0.50-5000 parts per billion (ppb), although one of the collaborating laboratories could not reliably quantitate below 1.0 ppb. Statistical analysis of the results showed that trigical reproducibility relative quantitate below 1.0 ppb. Statistical analysis of the results showed that typical reproducibility relative standard deviations (RSDr) ranged from 11 to 20% for both glyphosate and AMPA, which compares very well with predicted values for this concentration range. Total variability increased with increasing fortification level. The method has been adopted official first action by the Association of Official Analytical Chemists. DETERMINATION OF NITROAROMATICS AND NITRAMINES IN GROUND AND DRINK-ING WATER BY WIDE-BORE CAPILLARY GAS CHROMATOGRAPHY.

Army Environmental Hygiene Agency, Aberdeen Proving Ground, MD. Organic Environmental Chemistry Div. M. Hable, C. Stern, C. Asowata, and K. Williams.

Journal of Chromatographic Science JCHSBZ, Vol. 29, No. 4, p 131-135, April 1991. 5 fig, 3 tab,

Descriptors: \*Amines, \*Aromatic compounds, \*Drinking water, \*Gas chromatography, \*Pollutant identification, \*Water analysis, Detection limits, Laboratory methods, Nitrogen compounds.

A method was developed to determine the concentration of nitroaromatics and nitramines in drinking water at levels below those previously achieved by gas chromatography. The nitroaromatics and nitra-mines are extracted from water using toluene and mines are extracted from water using toluene and isoamyl acetale, respectively. The extracts are analyzed via a gas chromatograph equipped with a DB-1301 widebore fused-silica capillary column and an electron capture detector. Method detection limits of 0.003 micrograms/L for 2,6-dinitrotoluene, 0.04 micrograms/L for 2,4-dinitrotoluene, 0.06 micrograms/L for 2,4,6-trinitrotoluene, 0.3 micrograms/L for cyclotrimethylenetrinitramine, and 6.0 micrograms/L for cyclotetramethylenetetranitramine were obtained using this method. One of the benefits of using this method is that the use of small extraction volume generates a relatively small amount of hazardous waste. (Author's abstract) W91-11262

MARINE MONITORING IN HETEROGENE-OUS ENVIRONMENTS. EcoAnalysis, Inc., Ojai, CA

Marine monitoring programs around the city of Los Angeles' Hyperion municipal wastewater out-fall provide insight into important issues in moni-toring design. Historical monitoring programs

### **Group 5A—Identification Of Pollutants**

have produced information that was instrumental in making major management decisions about waste treatment policies. Consistent data collection over time has helped document trends in environ-mental conditions around the outfall. Designing mental conditions around the outrail. Designing monitoring programs to meet present needs re-quires both consistency and adaptive flexibility. Consistency is needed to track trends over time and to compare data from several studies. Changing management concerns require adaptation and flexibility to natural conditions. Decreasing populations of ridgebacked prawn used in the monitoring of contaminant levels in invertebrates around the outfall areas has necessitated changing the target species to crabs. Unlike the shrimp, the crabs can be collected by transing instead of trawlcrabs can be collected by trapping instead of trawling which is more cost-effective and trapping is less destructive to the ocean floor. Flexibility in sampling the microlayer for contaminants is needed to sample inside or outside visible slicks. Microlayer monitoring has been developed by regulatory agencies and incorporated into the NPDES permit for Hyperion. Monitoring of the NPDES permit for Hyperion. Monitoring of the infaunal community structure and biomass in the vicinity of the outfall helps to detect improvements or degradations in the water quality. Better estimates of biomass variability at a station are obtained by averaging replicate samples than by relying on a single sample. Ophiuroid biomass should be estimated with a regression equation to reduce sample processing time. Since environmental heterogeneity can complicate detection and description of changes in infaunal communities near sewage outfalls, ordination analysis of community data directly rather than analysis of variance should be used for improved monitoring results. DEVELOPMENT OF AN ENZYME IMMUN-OASSAY FOR THE DETERMINATION OF METAZACHLOR.

Technische Univ. Muenchen, Freising (Germany, F.R.). Lehrstuhl fuer Botanik. H. M. Scholz, and B. Hock.

Analytical Letters ANALBP, Vol. 24, No. 3, p 413-427, March 1991. 4 fig, 2 tab, 20 ref. Deutsche Forschungsgemeinschaft Grant Ho 383/26-1.

Descriptors: \*Analytical methods, \*Enzymes, \*Herbicides, \*Immunoassay, \*Metazachlor, \*Pollutant identification, Monitoring, Rabbits, Water

Immunological methods have several advantages over the classical procedures, such as gas chromatography and high-performance liquid chromatography, because of their simplicity, high sample throughput, and lower reagent costs. A sensitive, solid phase microtiter plate enzyme immunosasy (ELISA) was developed for determination of the behalvide and to the close the solid phase the (ELISA) was developed for determination of the herbicide metazachlor, which belongs to the class of alpha-chloroacetamides. The antisera were raised in rabbits by immunization with a metazachlor-BSA conjugate containing 27 metazachlor residues per molecule. A competitive ELISA with a peroxidase-metazachlor tracer was performed. Metazachlor could be detected within the range 0.01-1 micrograms/L. This fulfills the requirements of the European Community guideline for pesticide concentrations of 0.1 micrograms/L in drinking water. The midpoint of the calibration curve was 0.09 micrograms/L and standard deviations were very low, with percentage coefficients of variability low, with percentage coefficients of variability ranging from 2 to 6%. The test showed no crossreactivity with other structurally similar chloroa-cetamide herbicides and little cross reactivity with derivatives of metazachlor. The derivatives metazachlor hydroxide, metazachlor carboxylic acid and metazachlor methyl carboxylate showed cross reactivities of 13, 2.8, and 4.5%, respectively. The cross reactivities of metazachlor analogues, such as alachlor, metolachlor and butachlor, was below 1%. None of the assayed structurally unrelated compounds, such as atrazine simazine, prometryne, terbutryne and methabenzthiazuron, were crossreactive. (VerNooy-PTT) W91-11295

NOAA SATELLITE DATA IN NATURAL OIL SLICK DETECTION, OTWAY BASIN, SOUTH-ERN AUSTRALIA.

W. J. Perry, P. E. Williamson, and C. J. Simpson. BMR Journal of Australian Geology & Geophys-ics BJAGDT, Vol. 12, No. 1, p 25-33, 1991. 12 fig,

Crude petroleum in the form of thick oil or bitu-Crude petroleum in the form of thick oil of bitu-men seeps in places from the sea floor off southeast South Australia, and periodically strands on the coasts of South Australia, western Victoria and western Tasmania. In this pilot study, National Oceanic and Atmospheric Administration (NOAA) Advanced Very High Resolution Radi-context data consisted by the NAAA 0 architic (NOAA) Advanced Very High Resolution Radi-ometer data acquired by the NOAA-9 satellite, during the period of 13 days before to 1 day after a reported stranding of 1000 tons on Kangaroo Island, was studied to try to detect the floating crude, map its drift path, and determine the loca-tion of the seepages. The study's failure to detect any oil slick on the ocean surface is attributed to the prevailing high percentage of cloud cover and any oil slick on the ocean surface is attributed to the prevailing high percentage of cloud cover, and the calculated small area occupied by the slick in relation to the spatial resolution of the sensor, particularly after the oil had been degraded to bitumen. In the study area, continuing monitoring of locations and timing of strandings and the asso-ciated meteorological conditions, are needed if the sites of oil seepage are to be determined. In such cloud-prone areas, monitoring of petroleum slicks by remote sensing could require sensors operating in the microwave part of the electromagnetic spec-trum, but in areas with clearer skies the use of NOAA satellite data should be further investigated. If the locations of oil seeps can be thus identified, they may define locations of petroleum fields. Consequently, this type of investigation may be a relatively inexpensive exploration method in some offshore areas. (Author's abstract) W91-11296

STANDARD TEST FISH FOR INDIA AND THE NEIGHBORING COUNTRIES.

Nagarjuna Univ., Nagarjunanagar (India). Dept. of

Nagariana
Zoology,
A. S. Murty, and K. Kondaiah.
Bulletin of Environmental Contamination and

Among the battery of tests for environmental hazard evaluation of aquatic pollutants, the short-term or the 96-hour LC50 test with fish is one of term or the 90-nour LC30 test with itsn is one of the three base level aquatic toxicity tests that have to be conducted before registering a chemical for use in EEC (European Economic Community) countries. An evaluation was made of the suitabil-ity of some commonly occurring species of Indian fish for adoption as standard test fish for aquatic toxicity tests. The test fish (Danio devario (Hamiltoxicity tests. Ine test fish (Danio devarior (Hamilton), Esomus danricus (Hamilton), Chela atpar (Hamilton), Ambassis gymnocephalus Cuvier, Gambusia affinis (Baird and Girard), Puntius sofore (Hamilton), Oryzias melanostigma (McClelland), Aplocheilus panchax (Hamilton) and Puntius ticto (Hamilton) were collected from the Guntur canal or natural waterbodies around Nagarjuna University campus, Nagarjuna Nagar, South India. The calculated 96-hour LC50 of phenol for the nine species ranged from 5.6 to 30.6 mg/L. Five species were found to be unsuitable as standard test species were found to be unsuitable as standard test fish, due to non-uniform avoidance reactions and sensitivity to handling and acclimatization. The remaining four species, E. danricus, G. affinis, P. ticto and O. melanostigma, seem to be very well suited for being test fish as they could be easily transported to the laboratory, their mortality due to handling stress was negligible, no inexplicable control deaths were recorded, and the required age and size groups were available all through the year. Not only are the four species distributed all over the Indian subcontinent, but their distribution extends into neighboring Pakistan, Bangladesh, Nepal, Myanmar (Burma), Sri Lanka and Thai-land. PRECONCENTRATION OF HYDROPHILIC AND HYDROPHOBIC PESTICIDES FROM AQUEOUS SOLUTIONS AND EXTRACTION OF RESIDUES USING THE POLYMERIC SOR-BENT WOFATIT Y 77.

Akademie der Wissenschaften der DDR, Leipzig. Forschungsstelle fuer Chemische Toxikologie.

Forschungsstein tuer Chemische Toxikologie. W. Dedek, K. D. Wenzel, H. Oberlander, B. Mothes, and J. Mannig. Fresenius Zeitschrift fuer Analytische Chemie ZACFAU, Vol. 339, No. 4, p 201-206, February 1991. 7 tab, 16 ref.

Descriptors: \*Analytical methods, \*Chemical analysis, \*Pesticides, \*Pollutant identification, \*Proconcentration, \*Sorption, \*Water analysis, Gas chromatography, Herbicides, Insecticides, Pesticide residues, Plant tissues, Polymers, Radioactive tracers, Sediment analysis, Soil analysis, Thin layer chromatography.

Preconcentration of hydrophilic pesticides has been reported for the insecticides methamidophos, trichlorfon, dimethoate and the herbicides sodium trichloroacetate, fenuron, propachlor and 2,4-D. Meanwhile, the following compounds have been included in preconcentration experiments: dimethmetuded in preconcentration experiments dimensionation, methylparathion, bromophos, DDT, bromuron and lenacil from water in the concentration range between 0.05 micrograms/L and 1.0 mg/L; dimethoate and methamidophos from fruits and dimethoate and methamidophos from fruits and vegetables in the range of 0.2 mg/kg and dimethoate, propachlor and 2,4-D and a series of triazine, carbamate and urea herbicides from soils in the range of 0.2 to 1.0 mg/kg. The adsorption of dissociated compounds by polymeric sorbent Wofatit Y 77, depending on the pH intervals investigated, was effective for some compounds, but ineffective for ethephon, glyphosate, CCC and amirtole. Extraction of plant material using sodium chloride solution yielded recoveries of 65 to 95% of dimethoate, but for methamidophos, bound residues causing reduced recoveries have been obdues causing reduced recoveries have been ob-served. Optimal recoveries have been attained for extracting soils and sediments by mixtures of meth-anol or acetone with water. Studies were per-formed by using labelled compounds and thin-layer tornment by using latestier compounts and timi-ayer chromatography, whereas gas chromatography was effective for selected samples only, depending also on the type of detector used. metry, \*Water analysis, Detection limits, Metabolites, Monitoring.

Development and selection of detectors with satisfactory performance for the high-performance liquid chromatography (HPLC) analysis of pesticides and their metabolites are of importance for cottes and their metaconites are of importance for controlling the legal limiting values in environmen-tal samples. Studies have been carried out to com-pare different detection techniques including am-perometric detection in the reductive and oxidative mode and ultraviolet (UV) detection following the HPLC sengration of pesticides. By the example of HPLC separation of pesticides. By the example of 4,6-dinitro-o-cresol (DNOC), 2-sec-butyl-4,6-dinitrophenol (Dinoseb) and 2-tert-butyl-4,6-dinitrophenol (Dinoterb), it was shown that electrochemical detection exhibits higher sensitivities than the UV technique. The detection limits were 0.1 ng for Ov technique. The detection limits were 0.1 ing for pesticides using the amperometric technique, and 0.3 ng for DNOC and 1 ng for Dinoseb and Dinoterb using the reductive mode. By UV monitoring, the detection limits were 2 ng for DNOC and 24 ng for Dinoseb and Dinoterb. Thus, the and 24 ng for Dinoseb and Dinotero. It nus, the electrochemical method was found to be 20 to 240 more times more sensitive than the UV method. Furthermore, the reproducibility of the electro-chemical method was also better than that of the UV method. (Author's abstract)

MULTI-RESIDUE-ANALYSIS OF PESTICIDES BY HPLC AFTER SOLID PHASE EXTRAC-TION.

Descriptors: \*Analytical methods, \*Chemical analysis, \*Liquid chromatography, \*Pesticides, \*Pollutant identification, \*Separation techniques, \*Water analysis, Calibrations, Detection limits, Drinking water, Water quality monitoring.

In most countries of the European community, drinking water regulations set a limit of 0.1 microgram/L as the maximum level for individual pesticides and 0.5 microgram/L for the sum of all pesticides. To control and enforce legislation, a sensitive, universal and reliable analysis method is pesitiones. To control and reliable analysis method is required that can analyze a broad variety of substances in a single run. High-performance liquid chromatography (HPLC) has been found to be a good method for analyzing a broad variety of different pesticides in drinking and surface water. Since only a limited number of substances can be analyzed in a single run, one has to focus on the 20 to 30 compounds that are relevant in the water catchment area studied. Due to a high enrichment factor in solid phase extraction and the sensitive detection in the ultraviolet range, many pesticides can be determined even at a concentration lower than 0.05 micrograms/L. Use of a diode-array-detector enables acquisition of UV-spectra online and monitoring of signals for up to 8 wavelengths simultaneously. Thus for different classes of substances the best selectivity can be obtained by smuttaneously. Into for different classes of sub-stances the best selectivity can be obtained by choosing the appropriate wavelength with maxi-mum absorption. This aids in the identification of substances. In order to obtain the best quantitative accuracy each compound is calibrated at 5 levels from 0.025 to 1.000 micrograms/L. The detection limit is about 0.025 micrograms/L. (VerNooy-PTT) W91-11307

APPLICATION OF HPLC COLUMN-SWITCH-ING IN PESTICIDE RESIDUE ANALYSIS.

Rijksinstituut voor de Volksgezondheid en Milieu-hygiene, Bilthoven (Netherlands). E. A. Hogendoorn, C. E. Goewie, and P. van

Zoonen.

views, Sediment analysis, Selectivity, Sensitivity

The application of high-performance liquid chromatography (HPLC) for residue analysis is growing, especially for the analysis of pesticides which cannot be analyzed directly by gas chromatography due to poor volatility, polarity, and/or thermal instability of the compounds. An overview is given of the applicability of HPLC with column-switching in pesticide residue analysis. The main advantage of HPLC with column-switching is the enhancement of both sensitivity and selectivity combined with a high potential for automation, such as automated cleanup of extracts prior to LC analysis. Using relatively short columns (15x3.2 mm ID) as the first C18 column (C-1), mixtures of moderately polar pesticides not differing too much in retention can be sensitively analyzed in difficult matrices. The use of longer (50x3.0 mm ID) C18 columns as C-1, offers the possibility to perform an effective on-line cleanup for the simultaneous analysis of pesticides with a larger difference in retention. For the analysis of a single polar compound with little C18 retention, the use of this longer first C18 column appears to be very successful with respect to selectivity. In this case, the system behaves as a true multi-dimensional chromatographic separation. For this survey, column-switching conditions were mostly found by means of trial-anderror experiments. In order to find optimal conditions more easily, a computer program has been developed for predicting accurate peak volumes error experiments. In order to find optimal condi-tions more easily, a computer program has been developed for predicting accurate peak volumes and retentions under column-switching conditions. The method has been applied successfully to the analysis of pesticide residues in drinking water and sediments. (VerNooy-PTT) W91-11308

MULTIMETHOD FOR PESTICIDES IN SOIL

AT TRACE LEVEL.
ESWE-Inst. fuer Wasserforschung und Wassertechnologie G.m.b.H., Wiesbaden (Germany,

F.K.). H. Weil, and K. Haberer. Fresenius Zeitschrift fuer Analytische Chemie ZACFAU, Vol. 339, No. 6, p 405-408, February 1991. 3 fig, 4 tab, 1 ref.

Descriptors: \*Analytical methods, \*Fate of pollutants, \*Gas chromatography, \*Mass spectrometry, \*Path of pollutants, \*Pesticides, \*Soil analysis, \*Trace levels, Fungicides, Germany, Groundwater pollution, Herbicides, Insecticides, Rhine River, Scil cost-principies. Soil contamination.

During the subsoil transport of pesticides, adsorp-tion processes on solid phases are primarily respon-sible for the removal of pesticides. The adsorbed pesticides represent a latent risk to groundwater if maximal adsorption is reached and pesticides will desorb. A multimethod has been developed for the determination of various pesticides in deep layers of soil which occurred permanently or sporadically in the Rhine River. The soil samples were taken from the areas of a surface water works in October 1989 and extracted by using a Soxhlet apparatus. Quantitative determination of several pesticides Quantitative determination of several pesticides and other compounds, including simazine, atrazine, Metolachlor, Propham, Furalaxyl, diethyltoluamide, and tributyl phosphate, was achieved by the gas chromatograph (GC) with N/P-detector. Positive results were confirmed by the GC with mass spectrometry detector. Despite many years of pollution of the Rhine with pesticides and other substances, no pesticides sorbed on soil particles of the infiltration area were detected. The possibility of desorption, which can occur because of reversible adsorption equilibria, has to be rejected. The dominant factor in the elimination of dissolved contaminant so in the elimination of dissolved contaminants is not desorption, but dispersion. This process leads to the spreading of substances as they move with the water, and results in dilution of contaminant peaks, and in the attenuation of concentration. The groundwater passage of pesticides in low concentrations does not suggest a latent in low concentrations does not suggest a latent risk. The investigated substances are relatively polar (high water solubility) and have little tenden-cy to sorb (low soil adsorption coefficients). Results of the analysis support these assumptions.

DETERMINATION OF HERBICIDE RESIDUES IN SOIL IN THE PRESENCE OF PER-SISTENT ORGANOCHLORINE INSECTI-

Plant Protection Inst., Sofia (Bulgaria). A. M. Balinova, and I. Balinov. Fresenius Zeitschrift fuer Analytische Chemie ZACFAU, Vol. 339, No. 6, p 409-412, February 1991. 1 fig, 4 tab, 10 ref.

Descriptors: \*Gas chromatography, \*Herbicides, \*Organochlorine pesticides, \*Pesticide residues, \*Pollutant identification, \*Separation techniques, \*Soil analysis, Analytical methods, DDT, Organic Soil contamination, Water

A rapid and reproducible gas-chromatographic method has been developed for determination of residues in soil of some widely used herbicides such as trifluralin, metribuzin, alachlor, acetochlor, metolachlor, pendimethalin, simazine, atrazine, prometryne, in the presence of persistent organ-ochlorine insecticides (p.p-DDT, o.p-DDT, p.p-DDE, alpha-HCH, gamma-HCH, heptachlor). De-termination of some herbicides by gas chromatotermination of some heroicities by gas chromato-graph (GC/electron-capture detector (ECD) is difficult since their relative retention times on packed columns usually used for pesticide analysis are equal or close to those of some persistent organochlorine insecticides which can still be found almost everywhere, especially in cultivated soils. A 1.8 m column of 3% OV-225 + 5% SE-52 in a ratio of 1.4 to 0.9 gave good separation of all herbicides and insecticides mentioned. An examination was made of the influence of 6 solvents and nation was made of the influence of a solvents and solvent systems applied most frequently for soil extraction of pesticide residues on recovery of the compounds under study. Acetonitrile was the most suitable extractant as it rendered the highest residue recoveries and minimal amount of co-extrac-tives. Residues of simazine, atrazine, and prometryne were determined in the same extracts by the use of NP-detector and a column of 5% Carbowax 20M. Recoveries of the compounds under study were in the range 86%-103% without cleanup and were in the range 80%-103% without creanup and 78%-94% when cleanup was carried out. The method can be used in pesticide monitoring of soil as it offers an opportunity for rapid determination of soil applied herbicides and persistent organochlorine insecticides which are some of the most common pollutants in cultivated soils. # ANALYSIS OF 10 SELECTED HERBICIDES IN WATER.

J. Legler.

Fresenius Zeitschrift fuer Analytische Chemie ZACFAU, Vol. 339, No. 6, p 417-419, February 1991. 1 fig, 1 tab, 3 ref.

Descriptors: \*Analytical methods, \*Chemical analysis, \*Drinking water, \*Herbicides, \*Pollutant identification, \*Separation techniques, \*Water analysis, Chromatography, Gas chromatography, Germany, Laboratory methods, Liquid chromatography, Thin layer chromatography.

Since October 1, 1989, the German maximum res Since October 1, 1989, the German maximum residue level for each pesticide in drinking water is 0.1 micrograms/L, while the corresponding value for the total amount of all pesticides is 0.5 microgram/L. In three collaborative studies a method for the determination of pesticides in drinking water has been tested. For these studies 10 herbicides were chosen: atrazine, simazine, terbutylazine, cyana-zine, isoproturon, hexazinon, methabenzthiazuron, bromacil, dichloroprop, and mecoprop. They were chosen both because of their frequent application and their different chemical structures. For the and their different chemical structures. To the enrichment by solid phase extraction, surface modified silica gel was used by all participants, while for determination in the eluates, different methods of measurement were chosen, according to the available equipment of the analyst. Not all of the 10 spiked herbicides could be measured in the the to spiked neroscues could be measured in the eluates by all of the 13 participants of this study. Each participant used either capillary-gas chroma-tography (GC), high-pressure liquid chromatogra-phy (HPLC) or thin-layer chromatography (TLC).

#### Group 5A-Identification Of Pollutants

Analysis of the herbicides was achieved even at concentrations of 50 ng/L. Average recoveries were between 72% and 115%, with a relative standard deviation of about 21%. Gas chromatogstandard deviation of about 21%. Gas chromatog-raphy with a nitrogen-phosphorus sensitive detec-tor, a mass-selective detector, and an electron-capture detector is suitable for the analysis of triazines and other substances. Liquid chromatog-raphy (HPLC and TLC-AMD) is more suitable for the analysis of some polar or thermic unstable substances. So confirmation of one analytical result substances. So confirmation of one analytical result with a second independent measurement (for instance GC and HPLC) may be successful. An additional 70 pesticides were analyzed by participants of these studies. (VerNooy-PTT) W91-11311

STRATEGY FOR PESTICIDE CONTROL IN GROUND WATER AND DRINKING WATER. GROUND WATER AND DRINKING WATER. Karlsruhe Univ. (Germany, F.R.). DVG-Forschungsstelle am Engler-Bunte-Inst. H. J. Brauch, and S. Schullerer. Fresenius Zeitschrift fuer Analytische Chemie ZACFAU, Vol. 339, No. 6, p 420-422, February 1991. 5 fig, 9 ref.

Descriptors: \*Analytical methods, \*Chemical analysis, \*Drinking water, \*Groundwater pollution, \*Monitoring, \*Pesticides, \*Pollutant identification, \*Water analysis, Chromatography, Reviews, Separation techniques

Pesticide analysis in water is done by quantitative determination of individual compounds. Qualified methods like high resolution gas chromatography (HRGC), high performance liquid chromatography (HPLC), and thin layer chromatography (TLC) with excellent detectors are available. In some cases screening methods are used for groundwater control. With screening methods, carried out by special GC or HPLC methods, only qualitative results can be obtained. To get quantitative results, comparison of retention times and recoveries with standards is necessary. A useful monitoring strate-gy that can be carried out by quantitative determination has to include all important pesticides, such as atrazine, simazine, isoproturon, chlorotoluron, bentazone, and mecoprop. Since pesticides have different chemical properties, multi-methods have been developed, which allow the measurement of 'similar' substances. The use of a mass spectrome-ter or a mass selective detector is recommended, and identification of pesticides by ultraviolet (UV) spectra is possible using a diode array detector (DAD). It has been found that recoveries of the analyzed pesticides have to be controlled from time to time, and some extremely polar pesticides such as Amitrole, Glyphosate, etc. have not yet been successfully analyzed by multi-methods. SOLID-PHASE EXTRACTION FOR MULTI-RESIDUE ANALYSIS OF SOME TRIAZOLE AND PYRIMIDINE PESTICIDES IN WATER, mperial Chemical Industries Ltd., Bracknell (Eng-and). Plant Protection Div.

Baldy, Flaint Protection Div. E. Bolygo, and N. C. Atreya. Fresenius Zeitschrift fuer Analytische Chemie ZACFAU, Vol. 339, No. 6, p 423-430, February 1991. 8 fig, 2 tab, 9 ref.

Descriptors: \*Analytical methods, \*Chemical analysis, \*Groundwater pollution, \*Pesticide residues, \*Pollutant identification, \*Separation techniques, \*Triazine pesticides, \*Water analysis, Detection limits, Gas liquid chromatography, Liquid chromatography, Pesticides.

A multi-residue analytical method based on solidphase extraction (C18) has been developed for the analysis of 12 compounds in groundwater. These compounds are triazoles, e.g., diclobutrazol, flu-triafol, hexaconazole, paclobutrazol and its ketone triatol, nexaconazole, pactooutrazol and its ketone analogue and pyrimidines, e.g., bupirimate, pirimicarb, pirimiphos-methyl, ethirimol, and other pesticides: fluazifop-P-butyl, fluazifop and fomesafen. One liter of water modified with 1% methanol was extracted using a C18 solid-phase extraction column, containing 1 g of adsorbent. The retained compounds were eluted from the column with

accessive elutions of acetonitrile and methanol. No further cleanup was necessary. Residues were determined either by capillary gas-liquid chromatography (GLC) using a nitrogen-phosphorus selective detector, or high performance liquid chromatography (GLC) using a UV detector. Recovery data on these compounds were obtained by fortifying water at 0.05 to 100 microgram/L levels. Depending on the compound, mean recoveries were within the range of 80% to 107% with a coefficient of variation of 9% to 15%. The limit of determination, defined as four times the baseline noise, varied between 0.003 to 0.1 microgram/L also depending on the compound and detection sensitivity of the instrument. These recovery data have also been compared to values generated by conventional liquid-liquid partition. Various techniques were used to confirm the identity of these compounds. Gas chromatography-mass spectrometry (GC-MS) using selective ion monitoring (SIM) was used to confirm the compounds which were amenable to gas-liquid chromatography. These No further cleanup was necessary. Residues were was used to confirm the compounds which were amenable to gas-liquid chromatography. These were all the triazoles and bupirimate, pirimicarb, pirimiphos-methyl and fluazifop-P-butyl. HPLC methods were developed using different mobile phase and adsorbent combinations for the confirmation of ethirimol, fluazifop and fomesafen residues in water. (Author's abstract) W91-11313

SIMPLE SPECTROPHOTOMETRIC DETER-MINATION OF ENDOSULFAN IN RIVER WATER AND SOIL. Ravishankar Univ., Raipur (India). Dept. of Chem-

istry. J. Raju, and V. K. Gupta. Fresenius Zeitschrift fuer Analytische Chemie ZACFAU, Vol. 339, No. 6, p 431-433, February 1991. 1 fig, 1 tab, 12 ref.

Descriptors: \*Analytical methods, \*Chemical analysis, \*Endosulfan, \*Insecticides, \*Pesticides, \*Polutant identification, \*Soil analysis, \*Spectrophotometry, \*Water analysis, Adsorption, Chlorinated hydrocarbon insecticides.

Endosulfan (Thiodan), a broad spectrum chlorinat-ed insecticide containing sulfur, is used against many types of insect pests of plants and vegetables. A simple spectrophotometric determination of en-dosulfan is based on the liberation of sulfur dioxide dosuman is obsect on the floreration of stiff disorbed into an adsorbing reagent, malonyldihydrazide (MDH) and estimated by using p-amino azobenzene and formaldehyde to give a pink colored dye which has an absorbance maxima at 505 nm. Beer's Law is obeyed in the range of 1 to 6 ppm for a standard solution of endosulfan. The method can be easily applied in river water and soil samples to determine endosulfan levels as low as 0.5 ppm and 0.25 ppm in river water and soil, respectively. The method is free from the interference of most of the commonly used pesticides and foreign ions. Other organochlorine pesticides, organophosphorus pesticides, carbamates, ammonia, phenol, nitrate and phosphate do not interfere with the reaction. Aramite and other sulfur containing compounds, which easily liberate sulfur dioxide interfere with which easily liberate sulfur dioxide interfere with the reaction. The major advantages of the pro-posed method over the available spectrophotome-tric methods are the use of a simple apparatus for the liberation/absorption of sulfur dioxide, and the use of MDH (in place of glycerol-alkali) as an absorbing solution which has about 100% absorp-tion efficiency. MBAMT (N,N-methylene-bis(2-amino-5-mercapto-1,3,4-thiadiazole) is a new fungicide which is used to control rice bacterial leaf blight in China. A reversed-phase HPLC method is described for the determination of the fungicide MBAMT and its degradation product 2-amino-5-mercapto-1,3,4-thiadiazole (AMT) in water. The recoveries of the method for MBAMT and AMT lie between 90 +/-2.2% and 94.2 +/-2.2%; the theoretical detection limits for MBAMT and AMT in 100 mL samples are 2 ppb and 0.8 ppb, respectively. Column efficiency and detection sensitivity of this reversed-phase chromatographic method are better than methods using normal-phase modes. Hydrolysis and photodegradation studies of MBAMT in water were done in laboratory and field experisis and photodegradation studies of mPAM1 in water were done in laboratory and field experiments. The results from a model test-solution indicate that the degradation of MBAMT in water solutions of different ph values is very fast. These results agree with field test values, indicating that photodegradation is the main factor for MBAMT decomposition in the field and hydrolysis is of decomposition in the fleat and hydroysis is of minor importance. It is concluded that when used in conventional dosage, MBAMT, which is used in paddy fields in the south of China, should not be a hazard to the aquatic fauna and environment. (Ver-Noov-PTT)

NEW STANDARDS FOR THE DETERMINA-TION OF GEOSMIN AND METHYLISOBOR-NEOL IN WATER BY GAS CHROMATOGRA-PHY/MASS SPECTROSCOPY.

Commonwealth Scientific and Industrial Research Organization, Wembley (Australia). Div. of Water

W. Korth, K. Bowmer, and J. Ellis. Water Research WATRAG, Vol. 25, No. 3, p 319-324, March 1991. 3 fig, 3 tab, 16 ref.

Descriptors: \*Analytical methods, water, \*Measuring instruments, \*Odors, \*Radio-chemical analysis, \*Water analysis, \*Water quality monitoring, Deuterium, Gas chromatography, Mass spectrometry, Odor-producing algae, Stand-

Geosmin and methylisoborneol (MIB) are secondary metabolites of certain blue-green algae and actinomycetes that impart an earthy or musty odor to drinking water. Their odor threshold concentrations are 10-20 ng/L. As a consequence only the most sensitive methods will suffice for their analysis. Deuterium labelled geosmin and MIB have been synthesized and evaluated as internal standss. Deuterium incented geosmin and with nave been synthesized and evaluated as internal stand-ards in the determination of geosmin and MIB in water by closed loop stripping followed by gas chromatography/mass spectrometry (GC/MS). The labelled standards were compared with chlor oalkanes added at sampling time, the new standoalkanes added at sampling time, the new standards enabled accurate determination of the geosmin and MIB present initially, even when the samples were analyzed as much as three weeks later. The new standards gave better precision and accuracy than the chloroalkanes and overcame the underestimation of initial analyte concentration which usually results from losses of analyte through adsorption, volatilization, biodegradation, etc. during sample storage. Geosmin had a limit of detection of < 0.1 ng/L and 1 ng/L was determined with a coefficient of variation (CV) of 1.2% (n=5). MIB was determined at 1 ng/L with a CV (n=5). MIB was determined at 1 ng/L with a CV of 3.5% (n=5). Deuterium labelled standards offer many advantages over conventional internal stand-ards used for the determination of MIB and geosards used for the determination of MID and geos-min. They offer precision and accuracy at concen-trations below the threshold odor concentration, compensation for analyte loss during sample stor-age, and save time. The method could also be used to determine MIB and geosmin in food and beverages. (Doyle-PTT) W91-11329

GAMMARUS: ASELLUS RATIO AS AN INDEX OF ORGANIC POLLUTION.

Brighton Polytechnic (England). Dept. of Civil Engineering. I. T. Whitehurst.

Water Research WATRAG, Vol. 25, No. 3, p 333-339, March 1991. 8 tab, 16 ref.

## Identification Of Pollutants—Group 5A

Descriptors: \*Amphipods, \*Bioindicators, \*Isopods, \*Stream pollution, \*Water pollution effects, \*Water quality monitoring, Aquatic ecosystems, Nitrates, Nitrites, Organic pollutants, Phosphates, Pollution index, Riffle beetles, Riffles.

Gammarus pulex normally inhabits the well oxygenated riffle reaches of the river bed living between stones and is generally intolerant of organic pollution. Asellus aquaticus, however, is not normally considered to be a member of the riffle community but is usually found in the depositing substratum of pools. Asellus invades the modified riffle ecosystem as a part of the replacement community during organic enrichment and often becomes dominant. Large numbers of Asellus in the riffles therefore, are considered to be an indication of organic pollution. Macroinvertebrate populations including Gammarus pulex and Asellus aquaticus were surveyed at riffle sites on four lowland rivers, i.e. the Rivers Adur and Ouse and the Chess Stream, Sussex and the Eridge Stream, Kent. Sites were situated both upstream and downstream of sewage treatment works. Macroinvertebrates were collected using a Surber sampler and at some sites the water was analyzed for the main chemical constituents. Poor water quality is characteristically associated with low biotic scores and in this respect the Gammarus: Asellus ratio applied to riffle data corresponded with the Chandler Biotic Score Index and the Extended Trent Biotic Index. The Gammarus: Asellus ratio showed the closest correlations with concentrations of BOD, ammonia-nitrogen (NH3-N), nitrite-nitrogen (NO2-N) and phosphate-phosphorus (PO4-P) being sensitive to changes in water quality brought about by organic enrichment in the four rivers investigated. It is proposed that the Gammarus: Asellus ratio may provide a simple biological tool which could be used by anglers and other non-professional river users to routinely monitor water quality. Water Research WATRAG, Vol. 25, No. 3, p 355-357, March 1991. 2 tab, 17 ref.

Descriptors: \*Bacteriophage, \*Beach contamination, \*Bioindicators, \*Enteroviruses, \*Water analysis, \*Water quality monitoring, Analytical methods, Canada, Culturing techniques, Public health, Recreation facilities, Risk assessment.

In the past few years, the presence of enteric viruses has been noted in water quality studies of some Canadian bathing beaches. No correlation was found between the presence of these viruses and the fecal indicator bacteria. A correlation between the presence of of oliphage or other bacteriophage and enteric viruses has been indicated in recent studies. In particular, a single stranded RNA phage may serve the need to develop a more reliable and economical indicator for detecting public health risks from human enteric viruses. Five popular beaches in Southwestern Ontario, Canada, were investigated for the presence of coliphage, bacteriophage and the standard bacterial indicators of fecal waste. Using current phage enumeration techniques, both coliphage and bacteriophage were recovered at all five beaches on each of ten sampling trips. Coliphage and bacteriophage results were available in 6 to 18 h, respectively. The fecal coliforms required an incubation period of 24 hours. Based on recent reports on the association of coliphage and bacteriophage with enteroviruses in surface waters, and the consistent occurrence of both coliphage and bacteriophage at the five beaches investigated, future studies on the determination of health risks related to bathers, should involve virological analyses including the enumeration of coliphage and bacteriophage as part of the continuing evaluation of fecal pollution impacts on recreational waters. QUANTITATIVE DETERMINATION OF ACRYLONITRILE IN AN INDUSTRIAL EFFLUENT BY AMBIENT-TEMPERATURE PURGE AND TRAP CAPILLARY GC-MS AND BY HEATED PURGE AND TRAP GC-FID.

Air Products and Chemicals, Inc., Trexlertown, PA.

D. L. Vassilaros, T. J. Bzik, and C. A. Cara. Environmental Science and Technology ESTHAG, Vol. 25, No. 5, p 878-883, May 1991. 3 fig. 3 tab. 6 ref.

Descriptors: \*Acrylonitrile, \*Analytical techniques, \*Nitrogen compounds, \*Pollutant identification, \*Priority pollutants, \*Quantitative analysis, \*Wastewater analysis, Effluents, Experimental data, Gas chromatography, Mass spectrometry, Statistical analysis.

The commitment of regulatory agencies to minimize exposure to acrylonitrile (AN) has prompted the development of analytical methods to determine AN in water. The Environmental Protection Agency (EPA) has developed priority pollutant methods which are designed to analyze aqueous waste streams. EPA method 603 was specifically developed for the determination of AN and requires a heated purge cell, a packed column, and flame ionization detection. Another EPA priority method that may be useful for the detection of AN requires an ambient-temperature purge cell, a packed column, an internal standard, and mass spectrometric detection of the analytes (EPA method 624). The application of EPA method 603 to the routine determination of AN was evaluated for a specific waste effluent. This wastewater contained a complex mixture of nitrogen-substituted and oxygen-substituted aliphatic and alicyclic hydrocarbons. The effluent's chemical composition was significantly different from the effluent used in the laboratory evaluation of method 603. The consequent matrix effects forced fundamental modification of 603 instrumentation. The samples were then analyzed by a modified 624 method using capillary gas chromatography-mass spectrometry (GC-MS) and an ambient-temperature purge cell. Method validation data and a statistical analysis of data from calibration standard solutions analyzed over a 6-month period showed that the method was linear and had good sensitivity. The method precision determined from a series of standards yielded a 1 sigma relative standard deviation of 22%. (Korn-PT)

LOW COST FLOW INJECTION ANALYSIS FOR CADMIUM USING 2-(2-BENZOTHIAZO-LYLAZO) -4,5-DIMETHYLPHENOL.

Chiang Mai Univ. (Thailand). Dept. of Chemistry. K. Grudpan, and C. Paisaludomsil. Journal of Environmental Science and Health (A) JSSEDU, Vol. 26, No. 1, p 63-74, 1991. 9 fig, 2 tab, 23 ref.

Descriptors: \*Analytical methods, \*Cadmium, \*Chemical analysis, \*Heavy metals, \*Pollutant identification, \*Trace metals, \*Water analysis, Flow injection analysis, Instrumentation, Water quality monitoring.

Cadmium has become of great interest in various aspects of environmental studies because of its toxicity. A simple and rapid, but reliable method for determining cadmium is required. The advantages of flow injection analysis (FLA) such as small amounts of reagents and of the sample required, high rate of sample through-put and simplicity of instrumentation make it useful for the purpose. The reagent 2-(2-benzothiazolylazo)-4,5-dimethyl-phenol (BTDMP) has been reported as a sensitive and highly selective reagent for cadmium. BTDMP was synthesized and purified and dissolved in dimethylformamide (DMF). A stock solution of 1000 ppm Cd was also prepared and appropriately diluted for other standard solutions. In order to have a simple FIA set-up, reagents were combined into a one reservoir system containing BTDMP/DMF solution and a borate buffer. The effects of reagent concentration, buffers, tubing length, sample volume, flow rate, and interfering ions were studied. It was found that less than 0.1 ppm Zn, 0.007 ppm Ni, 0.3 ppm Cu, 0.1 ppm Co and 0.1 ppm Hg would not interfere with 3 ppm Cd. A calibration curve was constructed of standard cadmium solutions (0-10 ppm Cd). Resulting FIA peaks yielded a straight line up to 10 ppm. Stock solution of the reagent, BTDMP (0.00009 M) in aqueous DMF (40%) containing a borate buffer (PH = 9) can be stored for at least a week. A fresh solution of working reagent is recommended due to its stability. (Doyle-PTT)

TRACE ELEMENT DISTRIBUTION IN SURFI-CIAL SEDIMENTS OF THE NORTHERN TYRRHENIAN SEA: CONTRIBUTION TO HEAVY-METAL POLLUTION ASSESSMENT. Pisa Univ. (Italy). Dipt. di Scienze dell'Ambiente e del Territorio.

L. Leoni, F. Sartori, V. Damiani, O. Ferretti, and M. Viel.

Environmental Geology and Water Sciences EGWSEI, Vol. 17, No. 2, p 103-116, March/April 1991. 12 fig, 5 tab, 15 ref.

Descriptors: "Heavy metals, "Marine pollution, "Marine sediments, "Path of pollutants, "Trace elements, "Tyrrhenian Sea, "Water pollution sources, Barium, Bed load, Chromium, Cobalt, Copper, Lead, Nickel, Sediment contamination, Vanadium, Zinc.

The trace element distribution in bottom sediments of the northern Tyrrhenian Sea results from the influx of materials both from natural and anthropogenic sources. Over much of the basin, the surface Pb, Cu, Zn, and As contents appear considerably enriched relative to those below 15 cm; among these metals, Pb shows the highest and most wide-spread enrichment. Only in the case of some coarse-grained sediments close to the mouth of Cecina River it is possible to relate anomalouslyingh Zn contents to natural resources. In all other sampling stations, the enrichments of Pb, Cn, Zn, and As are ascribed to man's influence. The sediment distributions of Co, Cr, and Ni do not seem

#### **Group 5A—Identification Of Pollutants**

to be related to anthropogenic activities; rather they mirror influx of materials derived from sources of ophiolitic rock. The distribution of barium shows only two significant positive anoma-lies, and both are related to natural causes. Concentrations of vanadium are high in a zone close to an important smelting plant; these are thought to be of anthropogenic origin. The surplus of metal contamination introduced in the northern Tyrrhenian Sea from man's activities, although so far relatively small, in the long term could cause serious problems if effective measures to reduce pollutant releases are not adopted. MEASURING LOW RADON LEVELS IN

DRINKING WATER SUPPLIES.

Maine Univ., Orono. Dept. of Civil Engineering.

J. D. Lowry.

Journal of the American Water Works Association JAWWA5, Vol. 83, No. 4, p 149-153, April 1991. 3 fig. 1 tab, 11 ref. AWWA Research Foundation Project 529-89.

Descriptors: \*Drinking water, \*Laboratory methods. \*Radiochemical analysis. \*Radon. \*Water Descriptors: Drinking water, "Laboratory meun-ods, "Radiochemical analysis, "Radon, "Water analysis, Data acquisition, Liquid scintillation counting, Measuring instruments, Optimization, Radioactivity techniques, Standards, Water qual-

Because a relatively low maximum contaminant level (approximately 300 pCi/L) is expected to be set for radon in the near future, research was conducted with liquid scintillation counting (LSC) to determine whether this method of analysis could to determine whether this mendod of analysis could be used for low levels of radon. It was determined that significant improvement in the LSC analysis of Rn at low levels can be achieved through optimization of the protocol and counting parameters. The limited extraction of Rn into the counting fluor makes it important to maximize the water-to fluor ratio and minimize the air void in the countnuor ratio and minimize the air votal in the counting vial. This must be done in conjunction with an optimization of the counting parameters of the instrument. A water-to-fluor volume ratio of 17:5 was found to be optimum for the conditions used in this study. The often used ratios of 10:10 and 10:5 are not optimum for LSC analysis of Rn. 10:5 are not optimum for LSC analysis of Rn. Counting with an optimized window and an optimized water-to-fluor ratio gives a lowest quantifiable level of 150 pCi/L. For a 2-sigma total sampling, an analytical uncertainty of 15%, and a one half-life decay, a lowest quantifiable level of 90 pCi/L (actual) can be achieved. These values are for a 60-min counting period and duplicate analysis. Lower values can be achieved if the counting period is increased; however, the values cited are for cost-effective commercial analysis of large numbers of samples. (Doria-PTT) W91-11463

## LATEX AGGLUTINATION FOR THE DETECTION OF CAMPYLOBACTER SPECIES IN WATER.

WATEK.
Withington Univ. Hospital, Manchester (England).
E. M. Sutcliffe, D. M. Jones, and A. D. Pearson.
Letters in Applied Microbiology LAMIE7, Vol.
12, No. 3, p 72-74, March 1991. 1 fig, 2 tab, 5 ref.

Descriptors: \*Bacterial analysis, \*Campylobacter, \*Pollutant identification, \*Water analysis, Bacteria, Culturing techniques, Ducks, Laboratory methods, Microbiological studies, Temperature

The isolation of Campylobacter spp. from water samples is accomplished with conventional medial when appreciable numbers of organisms are present. A commercially available sensitized latex suspension could detect viable (100 organisms/mL) or heat-killed C. jejuni. C. coli, C. upsaliensis, and

Helicobacter pylori required at least 100,000 organisms/mL for agglutination, whereas with C. jejuni reactions were observed in suspensions of jejuni reactions were observed in suspensions of 100 organisms/ml. Boiling the bacterial suspensions of C. jejuni did not affect the latex agglutination of C. jejuni did not affect the viable counts. sions of C. jejum did not affect the latex agglutina-tion. Comparisons were made of the viable counts and the latex agglutination results obtained with three replicates of three microcosms. C. jejumi was recoverable by culture for up to 16 d from micro-cosms kept at 4 C but for less than half this time at higher temperatures. The latex test remained posi-tive throughout and showed no diminution after 6 tive throughout and showed no diminution after 6 months storage of the microcosms. Gram-stained films made after 18 d showed that the organisms were predominantly coccal in shape. Water samples from a small pond inhabited by ducks and moorhens regularly yielded cultures of C. coli and was never later-positive, nor were pure cultures of C. coli isolated from this source. Water from a lake C. coli isolated from this source. Water from a lake used for recreation and known to be fed by sewage-contaminated streams was usually both culture-positive and latex-positive. Cultures yielded a mixture of serotypes of C. jejuni with counts in the order of > 250 organisms/100 mL. Water samples taken from drinker lines from different sheds on 3 farms, yielded a small proportion of positive results. Prolonged culture of the latex-positive samples was unsuccessful. MONITORING OF ORGANOCHLORINE COMPOUNDS IN FINNISH INLAND WATERS POLLUTED BY PULP AND PAPER EFFLUENTS USING THE MUSSEL INCUBATION METHOD.

Water and Environment District of Central Fin-land, Jyvaskyla (Finland).

Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 397-402, 1991. 1 tab, 11 ref.

Descriptors: \*Bioassay, \*Chlorinated hydrocarbons, \*Finland, \*Freshwater mussels, \*Monitoring, \*Pollutant identification, \*Pulp and paper industry, \*Pulp wastes, Analytical methods, Biralytical of the compounds, Industrial Chlorinated aromatic compounds, Industrial wastes, Mining, Mussel incubation method, Polychlorinated biphenyls, Water quality control.

In the summer of 1988 a full-scale monitoring of chlorophydrocarbons, chlorophenols and aromatic chloroethers was carried out in the freshwater recipients of pulp and paper industry using the mussel incubation method, which has been developed and tested in Finland since 1984. The total number of incubation stations was 40. The results showed that the highest concentrations of chlorophenols originating from pulp bleaching processes were found in the vicinity of pulp mills with no biological wastewater treatment plant. Other chlorophenolic compounds (airborne or mainly originating from chloro-disinfection of water, combustion, wood preservation and sawmills) were detected in small amounts at almost all the sites tested. The highest concentrations were found in the recipients of old sawmills. PCB (polychlorinated biphenyi) was also detected in considerable concentrations in some recipients. Mussel incubation tests now constitute an important part of mon-itoring from environmental toxins in Finnish inland watercourses. The method is used in particular for monitoring recipients of the pulp and paper indus-try, but it is also suitable for the detection and try, but it is also suitable for the detection and monitoring of toxic pollutants from waste pits, sawmills, mining and metalworking industries and power stations, as well as for investigation and monitoring of the watercourse effects of agricultural pesticides. HIGH-PERFORMANCE LIQUID CHROMATO-HIGH-PERFORMANCE LIQUID CHROMATO-GRAPHIC STUDY ON OXIDATION PROD-UCTS OF LIGNIN AND HUMIC SUBSTANCES, Jyvaeskyle Univ. (Finland). Dept. of Chemistry. J. S. Knuutinen, and J. P. Mannila. Water Science and Technology WSTED4, Vol. 24, No. 3/4, p. 437-440, 1991. 1 fig. 5 ref.

Descriptors: \*Analytical methods, \*High performance liquid chromatography, \*Humic substances,

\*Lignin, \*Oxidation, \*Pollutant identification, \*Wastewater analysis, Degradation, Industrial wastes, Laboratory methods, Pulp and paper in-dustry, Pulp wastes, Water pollution sources.

A convenient method of preparing samples and characterizing the mixture of degradation products obtained from alkaline cupric oxide oxidation of water samples containing lignin and humic substances was developed. The method was applied to one unpolluted humic water sample and a total mill effluent of a kraft pulp mill. The fractions obtained by ultrafiltration were oxidized and the products contained on the products of degradation products have analyzed. (mixtures of degradation products) were analyzed by reverse-phase high-performance liquid chroma-tography. Acetonitrile-0.01 molar phosphate buffer (pH 2) was used as the cluent in a gradient system and ultraviolet (set at 280 nanometers) as the detec-tion system. Cupric oxide oxidation of a kraft pulp mill effluent produced many of the same com-pounds as were found in the unpolluted humic water. Differences in the chromatograms of the high molecular mass fractions of the samples studied can be used to characterize natural lignin and ubstances of various origins and to distinguish between natural humic matter and lignin compounds formed in the pulp industry. Because large amounts of vanillin were formed from kraft pulp mill effluent, is it suspected that chlorinated vanillins could be formed in cupric oxide oxidation of those effluents. If this proves true, the procedure might be useful of establishment of the transport of chlorolignin in waters downstream of the mill. (See also W91-11467) (Mertz-PTT) W91-11513

DIRECT SAMPLING ION TRAP MASS SPECTROMETRY FOR THE RAPID DETERMINATION OF VOLATILE ORGANICS IN ENVI-RONMENTAL MATRICES.

Oak Ridge National Lab., TN. Analytical Chemis-

M. V. Buchanan, and M. R. Guerin. Available from the National Technical Information Service, Springfield, VA. 22161, as DE89-015358. Price codes: A02 in paper copy, A01 in microfiche. Report No. CONF-8907123-1, (1989). 10p, 5 fig.

Descriptors: \*Ion trap mass spectrometry, \*Pollutant identification, \*Volatile organic compounds, \*Laboratory methods, Chemical analysis, Data acquisition, Measuring instruments, Mass spectrometry, Chlorinated aromatic compounds, Performance evaluation. Solvents.

Analytical methods are currently being developed for the rapid determination of part-per-billion (ppb) or lower levels of volatile organics (VOCs) in water, soil, air, and oil samples using direct in water, soil, air, and oil samples using direct sampling in combination with a rf quadrupole ion trap mass spectrometer (ITMS). Features of the ITMS which are important to the success of these applications include the ability to perform selective chemical ionization, high efficiency collision inchemical ionization, high efficiency collision in-duced dissociation (MS/MS) experiments, and excellent instrument reliability and tolerance to rela-tively high operating pressures. Excellent detec-tion limits, linearity of response, and reproducibil-ity have been demonstrated for the determination of volatiles in water, soil, and air. Because no chromatography is used, sample turn-around is typically < 5 minutes. Direct sampling is accomplished with a split-on-split capillary restrictor plished with a split-on-split capillary restrictor interface which has been designed to accept a wide variety of sampling devices. Volatiles in water can be determined without any sample preparation simply by direct purge and helium into the mass spectrometer sample interface. A helium flow rate of approximately 100 mL/min through a sparging device enables reproducible purging of volatiles from a 15 mL water sample in < 3 minutes. Soil samples are prepared by adding 15 mL of distilled water to 5 em of soil to form a shurry. Chlorinated water to 5 gm of soil to form a slurry. Chlorinated solvents have been successfully purged from samples of used motor oil without any sample prepara-tion. VOCs in air may be determined either by direct sampling or by preconcentration on a resin trap followed by direct thermal desorption into the ITMS. Direct air sampling has an estimated detec-tion limit of approximately 1 ppb, while precon-

Bulk precipitation has been collected continuously for chemical analysis on a storm event basis since 1979 at the Ward Valley Bench Station at Lake Tahoe, California. The station is 300 m higher than Tahoe, California. The station is 300 m higher than the lake, 6.8 km from the shore, and is only 3 km east of the Sierra Nevada divide. The 4 m high tower holding the sampler is in an extensive subalpine meadow surrounded by pine/fir forests; the closest development is low density housing 1 km to the northeast. Between 1979 and 1986, precipitation profile in progression in the profile of the specific profile in the specific profile. the northeast. Between 1979 and 1986, precipita-tion acidity increased significantly on the crest of the central Sierra Nevada. Variation in precipita-tion pH was closely associated with change in intrate concentrations but not with sulfate. This area of the Sierra Nevada crest contains many acid-sensitive, poorly buffered lakes and ponds that can be adversely affected by increasing precipita-tion acidity. (Mertz-PTT) W91-10471

Freshly collected leaves from a regenerating forest stand were treated with experimental acid rainfall of pH 4.6 in short-duration laboratory washing trials. The dynamics of initial sulfate and potassium trials. The dynamics of initial sulfate and potassium washoff from leaf surfaces were similar between elements and among species. Sulfate and potassium followed negative exponential foliar element washoff curves. Potassium leaching from foliage may occur with dry deposition washoff. The time for completion of the initial element washoff from leaves, in the range of 6-8 minutes, was similar to previously reported leaf immersion washing times. Potassium was washed from leaf surfaces at a faster rate than was sulfate. Tree species were Potassium was washed from leaf surfaces at a faster rate than was sulfate. Tree species were generally similar for dry deposition washoff amounts and rates within leaching trials. Washoff from lower leaf surfaces was negligible. The washoff curve analysis appeared to produce an accurate estimate of previous dry deposition to leaf surfaces, and eliminated many of the problems and limitations associated with bulk leaf washing impression approached. Authors bettered. mersion approaches. (Author's abstract) W91-10476

INTERANNUAL VARIABILITY IN ACIDIC DEPOSITION ON THE MT. MITCHELL AREA

DEPOSITION ON THE MIT. MITCHELL AREA FOREST.
North Carolina State Univ. at Raleigh. Dept. of Marine, Earth and Atmospheric Sciences.

Descriptors: \*Acid rain effects, \*Deposition, \*Forests, Canopy, Chemistry of precipitation, Cloud chemistry, Dry deposition, Mount Mitchell, Mountains, Nitrogen oxides, North Carolina, Ozone, Precipitation, Sulfur dioxide.

It has been suggested that forest decline at high elevation mountains in the eastern U.S. is associated with the deposition of acidic substances on the forest canopy through dry, wet and cloud deposition pathways. To determine the relative importance of these deposition mechanisms, a field study was initiated in May 1986, at Mount Mitchell, N.C. Since Mount Mitchell is frequently immersed in clouds (immersion time being in the range of 29-41%), the investigations were primarily focused on the collection of cloud water and the monitoring of meteorology and ambient air quality. The precipioners of the collection of cloud water and the monitoring of meteorology and ambient air quality. The precipioners are made to the collection of cloud water and the monitoring of meteorology and ambient air quality. The precipioners 41%), the investigations were primarily focused on the collection of cloud water and the monitoring of meteorology and ambient air quality. The precipitation data and related chemistry were obtained from a nearby NADP (National Atmospheric Deposition Program) site (Clingman's Peak). To estimate the dry and cloud deposition, the deposition relocities for gases and the rates of cloud deposition for cloud droplets were calculated with the ATDD (Atmospheric Turbulence and Diffusion Division, National Oceanic and Atmospheric Administration) model and a cloud deposition model. The wet deposition was obtained from NADP annual reports. Computations showed the deposition velocities for SO2, NO2, and O3 to be in the range of tenths of crn/second. The mean rate of cloud deposition was about 0.13-0.21 mm/hour. The rainfall ranged from 40 to 609 cm during the growing seasons (from mid-May to the end of September) of 1986-1988. Using these deposition fluxes of sulfur compounds were primarily contributed through the cloud capture mechanism (60%) followed by incident precipitation (25%) and dry deposition (15%). As to, the deposition (1980). followed by incident precipitation (25%) and dry deposition (15%). As to the deposition fluxes of deposition (15%). As to the deposition fluxes of nitrogen compounds, cloud deposition contributed about 50%, wet deposition about 25% and dry deposition about 25%. A comparison of deposition estimates at Mount Mitchell with those at other sites showed that the sulfate deposition at sites exceeding 1200 m above sea level in elevation in Bavaria, Germany and the eastern U.S. was almost identical within error limits. Ecological Modelling ECMODT, Vol. 52, No. 1/2, p 29-40, November 1990. 9 fig. 7 ref.

Descriptors: \*Computer models, \*Model studies, \*Municipal wastewater, \*Path of pollutants, \*Wastewater pollution, Argentina, Buenos Aires, Plysures, Simulation, Water currents, Water pollution sources. Wind.

A numerical technique based on the computation of contaminant dispersion in a localized area is examined. It allows a two-dimensional description of the plume when the dispersion scale is much smaller than the hydrodynamic one. The technique was implemented in the computational system MANCHAS, developed at the Laboratorio de Hidraulica Aplicada, and was applied to the plume generated by the sewage discharge of Buenos Aires city in the Rio de la Plata. The velocity and depth fields were achieved by the computational system HIDROBID II, also developed at the Laboratorio de Hidraulica Aplicada. The physical parameters involved in the phenomenon, such as dispersion coefficients and time of decay, were estimated from field measurements. Some numerical tests were performed for different tides and catmated from field measurements. Some humeri-cal tests were performed for different tides and wind velocities. It can be concluded from the results that the wind, as a generator of drift cur-rents, is the relevant mechanism of transport of the pollutant. (Author's abstract) W91-10488

OIL SPILLS IN MANGROVES: A CONCEPTU-AL MODEL BASED ON LONG-TERM FIELD OBSERVATIONS.

Sao Paulo Univ. (Brazil). Inst. de Biociencias C. M. Jacobi, and Y. Schaeffer-Novelli. Ecological Modelling ECMODT, Vol. 52, No. 1/ 2, p 53-59, November 1990. 1 fig, 11 ref.

Descriptors: \*Fate of pollutants, \*Mangrove swamps, \*Model studies, \*Oil spills, Coasts, Computer models, Oil pollution, Sediment contamination, Tidal effects, Tidal flats, Wetlands.

A conceptual model was proposed for evaluating the residence time of oil in mangrove environments. It assumed that, after oil had spread over a mangrove coastline, it remained in the environment by retention in the sediment. Removal was mainly in association with seaward particle export. Since detritus export depends on tidal flush, the area affected by an oil spill could be divided into sections parallel to the coastline having different removal rates increasing seaward (under little river flush and regular topography). The division of the total spilled area into segments allowed more complicated topography than a regular mild slope to be examined. In these cases, removal would still depend on tidal flush but not as a direct function of tidal amplitude. The model has to be improved with data on the concentration of oil in the field over time, for better estimations of removal rates over time, for better estimations of removal rates and related factors, and with calibration of detritus export in each segment, since these affect removal rates. Usually, in energetic models, only a general export rate is considered. (Mertz-PTT) W91-10489

The three elements carbon (C), nitrogen (N), and phosphorus (P), are very important in eutrophication in enclosed coastal areas. The primary source of C, N, and P is inflow from rivers, rather than release from sediment in the closed sea. In Japan, the environmental quality standards for organic pollution in rivers and seas are different. In a river, pollution in rivers and seas are different. In a river, organic pollution determination is based on BOD; in seas, organic pollution determination is based on alkaline COD. These different standards lead to difficulties in obtaining consistent water quality management of the water system from rivers to enclosed coastal seas. Hinuma River showed runoff loading of alkaline COD, BOD, C, N, and P in weekly observations in 1988 and 1989. When flow rate increases, increasing ratios are seen first in phosphorus, followed by carbon, then nitrogen. in phosphorus, followed by carbon, then nitrogen. Eighty-eight percent of the phosphorus runs off as particulate phosphorus; 84% of nitrogen runs off as dissolved nitrogen. Nitrogen runs off at an almost constant concentration, while most phosphorus runs off in high flow stages. The particulate phosphorus behavior after inflow to the enclosed coastal sea is an important factor in eutrophication. (Author's abstract)

Bohai Bay is one of the primary semi-enclosed coastal seas in China, situated in the west Bohai Sea and coast of Tianjin city, in the Hebong and Shandong provinces. With an area of 16,000 sq km, Beijing-Tianjin rivers polluted with effluent and storm runoff. Water quality surveys showed high levels of oil and trace metals, as well as elevated organic matter concentrations. These results indiorganic marter concentrations. These results mur-cated that despite Bohai Bay's assimilation and dilution capacity for pollutants, the pollution had led to higher levels of eutrophication, and fish and shellfish mortality. For the future, measures must be taken to reduce the amount of inorganic nitro-gen, inorganic phosphorus and organic pollutants discharged into the bay. (Brunone-PTT) W91-10522

CIRCULATION AND POLLUTANT DISPERSION IN MASAN-JINHAE BAY OF KOREA.
Korea Ocean Research and Development Inst., Seoul (Republic of Korea).

S. W. Kang.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p
37-40, 1991. 5 fig, 1 tab, 6 ref.

Descriptors: \*Dispersion, \*Hydrologic models, \*Korea, \*Marine pollution, \*Masan-Jinhae Bay, \*Model studies, \*Path of pollutants, \*Water circulation, Chemical oxygen demand, Salinity, Stagnant water, Tidal currents, Water currents, Water temperature.

Circulation and dispersion of pollutants in the Masan-Jinhae Bay, Korea (one of the most polluted water bodies in Korea) were studied through numerical experiments and hydrographic field surveys. The field survey includes the measurements of water level, currents, temperature, salinity and chemical oxygen demands (COD). To simulate the circulation and dispersion of pollutants discharged into the bay, a two-dimensional finite element scheme was employed. The calculated tidal cur-rents were consistent with the current meter measurements. Using the circulation model, dispersion of pollutants was estimated, resulting in very slow mixing with the open waters due to near-stagnancy of the inner bay waters. (Author's abstract) W91-10526

# NUMERICAL SIMULATION OF WATER QUALITY IN TOKYO BAY.

Japan NUS Co. Ltd., Osaka. N. Hamano, and Y. Nakagawa Marine Pollution Bulletin MPNBAZ, Vol. 23, p 45-49, 1991. 5 fig, 1 tab, 4 ref.

Descriptors: \*Japan, \*Marine pollution, \*Mathematical models, \*Model studies, \*Primary productivity, \*Tokyo Bay, \*Water quality, Limiting nutrients, Monitoring, Nitrogen, Nutrient concentrations, Organic loading, Particulates, Phosphorus, Water quality monitoring, Water quality standards.

The JATWEM model was developed to satisfy the need for a model that can be applied to all kinds of water bodies, and is easy to understand and use in water oddies, and is easy to understand and use in the evaluation of primary production. The model consists of an equation for total nitrogen and phos-phorus in a soluble state or as small particulates which act like water, and an equation for large particulates. The JATWEM model enables water quality to be calculated by an inductive parameter method based mainly on information obtained by field observation. Primary production is estimated from simulated values of total nitrogen and phosphorus. A calculation made for Tokyo Bay accurately predicted the water quality of the bay, alrately predicted the water quality of the bay, air though the calculated chemical oxygen demand value significantly exceeded the observed value, even though the concentration of nutrients were consistent with observed values. These results indi-cate that the model cannot evaluate consistently the actual primary production near inflow load areas when considering only nitrogen and phos-phorus as limiting factors. Descriptors: \*Coastal waters, \*Data interpretation, \*Ocean circulation, \*Path of pollutants, \*Remote sensing, \*Turbidity, Industrial development, Japan, Korea, Satellite technology, Sea of Japan, Seto

The Seto Inland Sea is the largest enclosed coastal area in Japan. It is bordered by an active industrial district, with many factories. The marine features of enclosed bays and coastal seas were investigated by satellite remote sensing. Turbidity in the Kanmon area and in Hiroshima Bay was estimated by using a new classification technique and verified with 'sea truth' data. Existing classification techniques for extracting information from satellite image data are almost all based on pixel-by-pixel processing; hence, data-processing time is very long. A new classification method, called the histogram overlay method (HOM), was developed. The HOM uses 'fuzzy likelihood' based on cell units comprised of several to hundreds of pixels. The performance of this method on a personal computer was compared with that for the most probable number (MPN) method. The new method was more stable given the noise and fluctuations of system parameters, in addition to requiring less computing time than the MPN method, and the computing time than the MFN method, and the results were almost the same as those from the MPN method. This technique was extended and applied to environmental researches on industrialized coastal areas of southern Korea which border the Sea of Japan. (Brunone-PTT) W91-10532

## FLUIDIZATION OF MARINE MUD BY

California Univ., Berkeley. Dept. of Civil Engi-

neering. H. T. Chou, J. R. Hunt, and M. A. Foda. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 75-81, 1991. 4 fig, 3 ref.

Descriptors: \*Marine sediments, \*Mud, \*Path of pollutants, \*Sediment transport, \*Suspended sediments, \*Wave effects, Fluid friction, Organic hydrocarbons, Polychlorinated biphenyls, Sediment-water interfaces,

Transport of soft marine mud is of concern because many water pollutants, such as trace metals, petro-leum hydrocarbons, PCBs and pesticides, are pre-dominantly associated with the surfaces of cohe-sive mud deposits. The structure of cohesive sediments is controlled by the input energy. At low oscillatory strains, cohesive sediment structure is described as an elastic solid. At higher oscillatory described as an elastic solid. At higher oscillatory strains, the sediment structure is viscoelastic, and at very high strain amplitudes, the sediment behaves as a viscous fluid. Rheological measurements of cohesive sediments provide a quantitative evaluation of these viscoelastic properties as functions of clay mineralogy, ionic strength of solutions, concentrations of solids, and oscillatory frequency. This viscoelastic representation of sediment structure can be used to predict the responses of such ture can be used to predict the responses of such sediments to oscillatory shear. # STATUS OF EUTROPHICATION IN THE GREAT BARRIER REEF LAGOON.

Queensland Univ., Brisbane (Australia). Dept. of Chemical Engineering.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p

#### Sources Of Pollution—Group 5B

89-93, 1991. 6 fig, 15 ref.

Descriptors: \*Australia, \*Eutrophication, \*Great Barrier Reef, \*Lagoons, \*Marine pollution, \*Path of pollutants, Cyanophyta, Nutrient concentrations, Phytoplankton, Runoff, Stream discharge.

Historical data on the levels of nutrients and phytoplankton in the Great Barrier Reef (GBR) lagoon indicates that background levels of phosphate-phosphorus and phytoplankton have increased significantly over the past 50 to 60 years and that the levels appear to be at or above the eutrophication threshold level for coral reef waters. Other data indicate that river discharge probably has a major impact on the nutrient status of the GBR lagoon, but other factors such as the nitrogen-fixing blue-green alga, Trichodesmium, so the could also be important. Trichodesmium has the ability to introduce large amounts of new nitrogen to the ecosystem, and phosphorus levels could be driving its growth. To date, little effort has been made to assess the impact of eutrophication on the toral reef communities. Because the background nutrient levels are relatively high, both runoff and sewage discharges could have serious impacts on nearby coral reef communities. Tertiary treatment, such as nutrient removal, of sewage should be required for all discharges in the vicinity of coral reefs and special precautions need to be exercised when designing runoff drainage systems. Descriptors: "Cycling nutrients, "Eutrophication, "Hiroshima Bay, "Japan, "Marine pollution, "Path of pollutants, "Water pollution sources, Nitrogen, Nutrient concentrations, Phosphorus, Phytoplankton, Primary productivity, Sediment chemistry, Seto Inland Sea, Suspended sediments, Water circulation

The Seto Inland Sea is bounded by Honshuu, Shikoku and Kyuushuu and has had increased levels of water pollution since the industrialization and urbanization began around 1965. Eutrophication in northern Hiroshima Bay, Japan, was investigated to provide information on nutrient budgets in aquatic circulation processes, i.e. primary production, settling flux of particulate organic matter (POM) and benthic remineralization. Primary production contributed to the organic pollution in the northern bay more than land-based organic loadings by a factor of ten. Approximately 60 to 70% of the POM originating in phytoplankton was easily remineralized into inorganic nutrients during the settling process in water. About 60% of the introgen and 70% of the phosphorus in benthic sediments could be returned to the water column. (Author's abstract)

HEAVY METAL POLLUTION IN SEDIMENT FROM THE SETO INLAND SEA, JAPAN.

To evaluate the geochemical and environmenta behavior of heavy metals in the Seto Inland Sea

To evaluate the geochemical and environmental behavior of heavy metals in the Seto Inland Sea, the largest semi-enclosed coastal sea in Japan, distributions of heavy-metal pollutants were examined and mass balances of zinc and copper were studied by applying a simple box model. According to core samples, increases in the heavy-metal content

of sediments had already started by the late 1800's and are thought to have been due to human activities. Recently, sediment pollution in Osaka Bay (which is the most contaminated area in the Sea) has tended to decrease. In 1980, total sediment loads of copper and zinc over the whole area of the Sea were estimated to be 630 and 3500 tons per year, respectively. Furthermore, the sediment loads due to human and non-human activities were estimated separately to be 310 and 320 tons per year for copper, and 1700 and 1800 tons per year for zinc. Total inputs of copper and zinc into the Sea were estimated to be 870 and 4250 tons per year, with about one-half being the results of human activities. Seventy percent of the copper input and 80% of the zinc input are accumulated in the sediments. (Author's abstract)

SCAVENGING PROCESSES OF MARINE PAR-TICLES IN OSAKA BAY. Kagawa Univ., Miki (Japan). Faculty of Agricul-

ture. S. Montani, Y. Mishima, and T. Okaichi. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 107-111, 1991. 3 fig, 4 tab, 8 ref.

Descriptors: \*Biotransformation, \*Fate of pollutants, \*Marine sediments, \*Nutrient transport, \*Osaka Bay, \*Particulate matter, \*Path of pollutants, \*Pollutant scavenging, Cycling nutrients, Japan, Nitrogen, Sedimentation, Tidal effects.

The fate of pollutants introduced into Osaka Bay by human activities was investigated using integrated studies of scavenging mechanisms and biotransformation processes. Scavenging by marine particles was studied using nutrient (C, N, P) distribution as an indicator. Nutrient concentrations in the water and on suspended particles, on settling particles, and in surface sediments were monitored for three years (1985 to 1987). Large variations were found which appeared to depend on environmental conditions. Nutrient concentrations on suspended and settling particles decreased from the inner part of the bay to the offshore area. The position of the tidal front in Osaka Bay agreed very closely with the 20 to 30 m depth; the chemical character of suspended and settling particles was considerably different outside vs. inside the tidal frontal area. At the offshore station, settling particles were mainly 'old particles' in which the labile organic matter fraction was already decomposed. Sedimentation of nitrogen in the inner part of the bay accounted for approximately 6% of all nitrogen inputs to Osaka Bay. Thus, marine particles are very important in nutrient scavenging and cycling in Osaka Bay. (Author's abstract)

PRESENT STATE OF ENVIRONMENTAL POLLUTION IN COASTAL SEA AREA AND MEASURES FOR PROTECTION.

Institutul Roman de Cercetari Marine, Constanta (Romania).

(Romania). P. E. Mihnea, E. Cuingioglu, and I. Pechneanu. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 117-121, 1991. 5 fig, 5 tab, 12 ref.

Descriptors: \*Black Sea, \*Coastal areas, \*Eutrophication, \*Nutrient concentrations, \*Path of pollutants, \*Water pollution control, Biological wastewater treatment, Chlorophyll a, Heavy metals, Outfall, Phytoplankton, Toxicity, Wastewater treatment.

The eutrophication process in the Black Sea has accelerated for twenty years, since urbanization and industrial development has begun. Extensive and increased nutrient input into the Black Sea over the last two decades has led to elevated nutrient concentrations. The highest levels were found in front of outfalls or in shallow areas. A comprehensive scientific survey, with about thirty parameters, over a time period of 1979 up to 1989 has been developed, as well as experimental work to test the influence of the main polluting compounds on the marine organisms. Phytoplankton communities developed high population densities, with high levels of chrysophytes and cryptophytes. Large standing crops led to high concentrations of

chlorophyll a. The final outcome was suboxic, marine organism mortality and decreases in the number of landed fish. Ecotoxicological tests must include all the parent chemical compounds or breakdown products that may affect the natural environment. Improvements to the water quality could be made by filtration and irrigation to remove residual biological solids from effluent, advanced treatment of sewage and industrial wastes to remove almost all the phosphorus by precipitation; and development of new treatment technology to remove nitrogen compounds and heavy metals. Descriptors: \*Algal blooms, \*Bedford Basin, \*Copper, \*Decontamination, \*Nova Scotia, \*Path of pollutants, \*Phytoplankton, \*Trace metals, Algal growth, Coastal waters, Primary productivity, Stream discharge, Toxicity.

Phytoplankton during a bloom have been hypothesized to decrease the concentration of toxic free copper ions by releasing organic chelates that coordinate the copper and thereby detoxify the water. The concentration and speciation of dissolved copper was measured in Bedford Basin, Nova Scotia during the spring phytoplankton bloom of 1987 using in situ extraction techniques. The results indicated little change in the concentration of copper bound by organic chelators extractable by reverse phase techniques during the growth period of the bloom. The concentration of total dissolved copper and organic bound copper in this system was controlled by local fresh water inputs. The total concentration of copper was found to vary from 5 nM to 10.5 nM, concentrations typical of coastal waters. Primary productivity has a secondary impact. (Brunone-PTT)

LIFE CYCLE STRATEGIES OF THE RED TIDE CAUSING FLAGELLATES CHATTONELLA (RAPHIDOPHYCEAE) IN THE SETO INLAND SFA

Nansei Regional Fisheries Research Lab., Hiroshima (Japan).
C. Imai, S. Itakura, and K. Itoh.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 165-170, 1991. 6 fig, 19 ref.

Descriptors: \*Algal blooms, \*Biological pollution, \*Coastal waters, \*Flagellates, \*Japan, \*Life history studies, \*Path of pollutants, \*Red tide, \*Seto Inland Sea, \*Water pollution effects, Algal growth, Dormancy, Fish farming, Life cycles, Mortality, Seasonal distribution, Sediments.

Chattonella antiqua and Chattonella marina are the most noxious red tide flagellates, causing serious damage to fish farms, especially yellowtail fisheries, in Japanese coastal waters such as the Seto Inland Sea (SIS) during the summer. Cysts of Chattonella were identified from sediments of the SIS. These cysts overwinter on the sea bottom and play an important role in initiating summer red tides. Most of the cysts adhere to solid surfaces such as diatom frustules and sand grains, which may aid in keeping the cyst populations within seed beds for the red tides. Temperature is a principal factor affecting the physiology of cysts of Chattonella. No cysts germinate at 10 C. Optimum temperature range is between 20 C and 25 C for germination. For maturation (acquisition of germination) of the cysts, low storage temperature of 11 C or below for more than four months is essential, whereas no significant maturation is observed at 20 C or more. In freshly collected sediments, marked seasonality of germination was confirmed in Suo-Nada. The cysts spend a period of spontaneous

#### **Group 5B—Sources Of Pollution**

dormancy between autumn and the next spring, and they mature during the winter season. The life cycle of Chattonella is therefore well-adapted to the seasonal temperature fluctuation in the SIS. Furthermore, alternation between the benthic and planktonic stage is unconstrained by the shallow-ness of the SIS. The life cycle of Chattonella can be regarded as a superior life history strategy for the occurrences of red tides in temperate waters like the SIS. (Author's abstract) W91-10546

LONG TERM ECOLOGICAL CHANGES IN THE GULF OF THAILAND.
Department of Fisheries, Bangkok (Thailand). Marine Fisheries Div.

S. Suvapepun.
Marine Pollution Bulletin MPNBAZ, Vol. 23, p 213-217, 1991. 6 fig, 2 tab, 9 ref.

Population density, Species diversity

The Gulf of Thailand is a tropical enclosed sea in the southwestern part of the South China Sea. The the southwestern part of the south China Sea. I ne increasingly deteriorated conditions in the coastal environment have raised concerns among scientists and the public. The frequency of algal blooms has markedly increased in some estuarine and mangrove areas corresponding to the increase in nutrient loading. Patterns of change in the biomass of phytoplankton are linked to the increased nutrient. discharge in the Inner Gulf. The changes in species composition of demersal fishes and benthic communities, and large decreases in population sizes or even disappearance of species have also been noted in this area. Bivalve fisheries had deteriorated as in this area. Bivalve fisheries had deteriorated as early as 1970, due to the organic pollution discharged directly in the form of river outflow to the sea. The decline of fisheries in the Gulf of Thailand is primarily caused by overfishing; however, discharges of organic pollutants from cities and industries have caused marine pollution in some estuarine and coastal areas and have impacted the coastal aquaculture activities and bivalve fishery. The long coastline of the Arabian Sea along the west coast of India has numerous enclosed areas and inlets where threats of crude oil pollution have increased in severity for the last few years. The oil pollution generally originates from harbors and marine terminals, offshore oil wells, oil tanker dis-asters, and land sources. The enclosed regions of inlets are heavily exposed to crude oil pollution caused by tankers carrying oil from the Middle East oil fields to the South West Asia and Far East. The degradation of oil involves both bacterial utilization and partial dissolution. The low boiling saturated hydrocarbon fractions of crude oil caused mortality in a wide variety of fish and shrimp fry. The worst cases were the larvae that nad deformed bodies and abnormal flexures of the tail, were unable to swim normally and most died within one day. The hydrocarbon content of the Indian seafood ranges from 0.6 to 3.0 mg/kg wet weight. (Author's abstract)

Jinhae Bay, the largest bay in Korea, was once a Jinhae Bay, the largest bay in Korea, was once a productive area for fisheries. From the industrial area around Masan Bay, approximately 200 cu m waste per day discharges into the bay, about 75% of that comprising municipal sewage. In addition, 711 kl human wastes flows into the bay, with about half remaining untreated. Chemical oxygen demand, phosphorus and sulfide contents increased demants, prospined and admit contents increased for the last decade (from 1972 to 1982). Mariculture in Korea (mostly in seaweed, oysters, mussels, arkshells) increased almost eightfold for the last two decades. Red tides have frequently occurred, with more than 50% of the red tides located in Jinhae Bay. Causative organisms of red tides shifted from diatoms to flagellates. A decrease in shell-fish production and mass mortality of other organisms was caused by a high level of eutrophication, resulting from both waste discharges from an industrial complex and organic deposits from aquaculture. Potential pollution control measures include widescale dredging in the Masan Harbor and cleaning of bottom deposits in aquaculture grounds with specially-designed boats. (Brunone-PTT) W91-10558 with more than 50% of the red tides located in

Measurements of persistent litter on 13 beaches in Spain, Italy (Sicily), Turkey, Cyprus and Israel between 1988 and 1989 show that plastic items are the most abundant in the litter composition, folthe most adminant in the fitter composition, rot-lowed by wood, metal, and glass items. Remnants of fishing gear are rather rare. The quantity of litter on a beach is inversely related to its geo-graphical distance to a population center and di-rectly related to its number of visitors. Seasonal fluctuations in coastal litter are caused by storm waves which wash the litter landward, leaving the waves which wash the litter landward, leaving the beach clean during winter, and by bathers who pollute the beach during summer. Based on the nature of the garbage, most Mediterranean coastal litter is land-based, in contrast to the reported marine-based litter on the western European shores. (Author's abstract) W91-10569

Omura Bay is a typical enclosed inner bay. Thermal stratification begins gradually in the central part of the bay in May when the water temperatures increase between the surface and the bottom water. Oxygen-deficient water in the bottom layer is renewed every summer. In August, the degree of oxygen deficiency is highest. Nutrients (phosphate phosphorus and ammonia nitrogen) are released from the bottom sediments under these anaerobic conditions. The water circulation begins in Octo-ber and November. The anaerobic condition of the water is sometimes influenced by wind. Low dis-solved oxygen concentration in the surface water solved oxygen concentration in the surrace water was observed when an upwelling of oxygen deficient water was caused by a drift current. Formation of oxygen deficient water masses during the summer influences marine organisms in the bay. The circulation of the water mass in autumn accelerates the occurrences of red tides. Two different types of semi-enclosed, organically polluted bays were investigated in the northern part of the Sea of Suo, the Seto Inland Sea. One is Tokuyama Bay, surrounded by industrial complex-

#### Sources Of Pollution—Group 5B

es; the other is Yamaguchi Bay, seemingly affected mainly by household effluent draining through many rivers. Little sea water exchange was ob-served in Tokuyama Bay. During the summer, vertical mixing was weak, because of thermal stra-ification. Dissolved oxygen concentration was low ification. Dissolved oxygen concentration was low in the bottom water layer; primary production was constant throughout the year. In Yamaguchi Bay, the exchange rate of sea water was relatively high and the contribution of primary production to the organic pollution in the bay was small. Pollutant load by domestic sewage had a major influence on the sea water quality. (Author's abstract) W91-10593

Pollution in the North Sea comes from various Pollution in the North Sea comes trom various sources: atmospheric deposition, riverine input, and direct discharge from industries or ships. An integrated concept is proposed, combining field observations and the application of numerical models for transport processes in tidal rivers, estuaries, and the North Sea. The observation system consists of highly sensitive devices operated in boats in rivers and estuaries to determine transport rates and net transport of water constituents. In situ measurements are combined with moored sys-

tems and analysis of samples. Hydrodynamic pa-rameters are measured by horizontal and vertical profiling. The numerical models are based on shal-low water equations and solved by a finite differ-ence scheme. They use an implicit formulation of the free surface variation and allow for an economic time stepping procedure and treat flooding and falling dry of tidal flats. Transport of conservative taling dry of toda hats. Iransport of conservative substances is simulated using a tracer random walk technique. Transport of non-conservative substances can be achieved with a one-dimensional model of the upper part of the estuary. The suspended matter transport model uses current fields computed by a three-dimensional, time-dependent model of the northwest European shelf sea. (Brun-

Hypothetical oil spill trajectories are projected for ryporteneas or spin trajectories are projected for each monsoon from four locations near Japan: the central and southern Sea of Japan, and the north-ern and southern East China Sea. Actual and possi-ble maritime jurisdictional boundaries were superimposed on these trajectories. The trajectories indi-cate the distance of travel from the site in three day intervals, usually up to thirty days, or until little further movement is expected. The models include the effects of regional currents, circulation patterns derived from simplified circulation models of the region, statistical or climatological winds, and a hypothetical weathering process for an inter-mediate weight crude oil. Spills at most sites would soon cross international jurisdictional boundaries and may eventually reach a sometimes estranged neighbor's coast. These results indicate that cooperation is necessary among East Asian countries to minimize the effects of such a spill. (Brunone-PTT) W91-10608

During 1981-1988 in the United States, 248 water-During 1961-1968 in the United States, 2-86 water-borne outbreaks occurred in community (45%) and noncommunity (34%) water systems and from the ingestion of contaminated water from individual (11%) and recreational (10%) water sources. The (11%) and recreational (10%) water sources. In ease of contaminated, untreated groundwater or inadequately disinfected groundwater was responsible for 44% of the waterborne outbreaks reported during this period. The use of contaminated, untreated surface water or inadequately treated surface water was responsible for 26% of the outbreaks during this period. Contamination of the distributions and the contamination of the distributions and the contamination of the distributions. distribution system, primarily through cross-con-nections and repair of mains, caused 13% of the nections and repair of mains, caused 13% of the outbreaks. The remaining outbreaks were caused by miscellaneous and undetermined deficiencies. During 1981-1985, a dramatic increase in outbreaks occurred in filtered water systems, underscoring the importance of proper design and operation of filtration facilities. Since the 1940s, most water-borne outbreaks resulted in acute gastroenteritis of undetermined etiology, representing a combination undetermined etiology, representing a combination of viral, bacterial, and parasitic etiologies. Recognized waterborne pathogens include Norwalk agent, rotavirus, Campylobacter, Yersinia, Giardia, and Cryptosporidium. Enterohemorrhagic E. coli

Descriptors: \*Drinking water, \*Epidemiology, \*Human diseases, \*Public health, \*Water pollution effects, \*Water quality standards, \*Water treat-ment, Filters, Filtration, Microbiological studies, Reverse osmosis, Surveys, Water distribution.

A prospective epidemiological study was undertaken to evaluate whether drinking water satisfying current quality standards nevertheless causes gastrointestinal illness. The study consisted of a health surveillance of 600 randomly chosen househealth surveillance of 600 randomly chosen house-holds (2,400 individuals) and of the microbiological analysis of tap water from the filtration plant and its distribution system. Half of the households were randomly assigned to the tap water subgroup and half to a control subgroup. A reverse osmosis filter was installed in each control household, thereby was installed in each control household, thereby ensuring a very low microbiological pollution level. Each member of each household reported gastrointestinal symptoms on a bimonthly health calendar during two periods. The incidence of highly credible gastrointestinal symptoms (HCGI) was markedly different in the two groups. During the first period the incidence of episodes/year was 0.82 in the group consuming filtered water and 1.13 among those consuming the respectively 0.47 except prior these values were respectively 0.47. 1.13 among those consuming fap water. During the second period these values were respectively 0.47 (filter) and 0.62 (tap). Differential incidence rates of HCGI between the two groups were observed in all age and sex groups. While tap water met acceptable standards of quality, these results indicate that there was a 25% excess of gastrointestinal illness in the group consuming the water. Further analysis of the water quality and of the integrity of the distribution system are underway. Serum samples are also being analyzed. (See also W91-10612) (Author's abstract)

STAPHYLOCOCCI IN POLLUTED WATERS AND IN WATERS OF UNINHABITED AREAS, National Board of Waters and the Environment, Helsinki (Finland).

J. Ahtiainen, M. Niemi, and H. Jousimies-Somer. Water Science and Technology WSTED4, Vol. 24, No. 2, p 103-108, 1991. 3 fig, 3 tab, 15 ref.

Descriptors: \*Fecal bacteria, \*Path of pollutants, \*Rural areas, \*Staphylococcus, \*Water pollution sources, Culture media, Finland, Lakes, Streams, Survival, Wastewater.

The occurrence of staphylococci was studied in The occurrence of staphylococci was studied in southern Finland using both the modified Vogel-Johnson (VJP) and the M-5LSMA media in the MF technique. The study involved brooks and small lakes in uninhabited areas and sparsely populated farming areas as well as effluents from sewage treatment plants. Fecal indicator bacteria were determined simultaneously in all samples. Median colony counts on both of the staphylococal media in 100 ml samples were 1 to 2 for uninhabited areas, 60 to 110 for agricultural areas, and 1,000 to 1,600 for treated wastewater. The maximum values were much higher in all the enviand 1,000 to 1,600 for treated wastewater. The maximum values were much higher in all the environments. The M-5LSMA recovered at least as many staphylococci as the VJP medium, but was more selective. Strains isolated from pristine waters and from wastewater were identified with the API 20 Staph kit. Six different species of staphylococci were recovered on the VJP medium and ten on the M-5LSMA medium. About one-third of the isolates from wastewater were Staphylococcus areus, whereas 1896 of the isolates from lococcus aureus, whereas 18% of the isolates from uninhabited areas belonged to this species. The identification was confirmed with the coagulase and DNAase tests. Different survival and adher-

ence properties between staphylococci and fecal indicators may explain the higher staphylococci/ fecal indicator ratio in cleaner waters than in treated sewage. The origin of staphylococcal contami-nation and the evaluation of the indicator value of w91-10631

STUDIES ON THE BACTERIAL FAUNA OF THE TAMAGAWA RIVER, Meiji Coll. of Pharmacy, Tokyo (Japan). Dept. of Microbiology.

T. Arai.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 109-112, 1991. 5 tab, 1 ref.

Descriptors: "Path of pollutants, "Stream biota, \*Tamagawa River, \*Water pollution sources, Ag-ricultural runoff, Arsenic, Bacteria, Coliforms, Fish farming, Heavy metals, Japan, Mercury, Pes-ticides, Seasonal variation, Wastewater treatment.

Bacteria of the Tamagawa River near Tokyo were studied to assess contamination from different sources. Water from 8 sampling points was examined in spring, summer, and autumn. Bacteria were distinguished by their colony forms on selective media containing various drugs, including mercuric chloride (Hg), sodium arsenate (As), furazolidone (NF), streptomycin, kanamycin, chloramphenicol, tetracycline, ampicillin, and sodium dependent of the strength of the stre phenicol, tetracycline, ampicillin, and sodium do-decyl sulfate. Pollution from fecal materials was determined using coliforms and Enterococcus. The major part of these bacteria came from human sources and not from domestic animals. Hg and As sources and not roll domestic administ. If and As are used as pesticides; NF is used mostly for fish. The high incidence of NF-resistant bacteria in spring could be an indication of high activity of hatcheries. Some of the heavy-metal-resistant bacnatcheres. Some of the neavy-metal-resistant bac-teria could come from soil, transported by summer rains, because these pesticides are used in agricul-tural fields in the late spring and summer after the rice fields have been drained. Results suggest that general bacteria in the Tamagawa River originate mainly from fish culturing and agriculture, and that coliform bacteria are mainly of human origin. Wastewater treatment seemed to be effective in reducing bacterial contamination. It is hoped that reacting outcome contamination. It is hoped that this investigation will lead to the development of a new system for the detection of river water pollu-tion. (See also W91-10612) (Doria-PTT) W91-10632

BACTERIAL WATER QUALITY IN URBAN RECEIVING WATERS, Middlesex Polytechnic, Enfield (England). Urban Pollution Research Center.
J. L. Jacobs, and J. B. Ellis.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 113-116, 1991. 4 fig. 7 ref.

Descriptors: \*Path of pollutants, \*Receiving waters, \*Urban areas, \*Urban watersheds, \*Water pollution sources, \*Water quality standards, Bacteria, Benthic environment, Bioindicators, Coliforms, England, Fecal bacteria, London, Microorganisms, Pathogens, Public health, Risk assessment, Salmonella, Sediments, Storm runoff, Streptococcus.

A health risk assessment was conducted for an urban catchment located in the northwestern fringes of metropolitan London, England. Monthly samples of water and sediment were analyzed for samples of water and securities were analyzed to total and fecal coliforms, fecal streptococci, and selected pathogens. The waters within the Silk Stream catchment were judged to be severely pol-luted, and can exceed the European Economic theet, and can exceed the European Economic Community (EEC) guideline limits for both total and fecal coliforms, fecal streptococci, and Salmonella throughout the study area during storm flows. The EEC guideline limit for fecal coliforms of 100 MPN/100 ml is exceeded more than 80% of of 100 MPN/100 ml is exceeded more than 80% of the time with rainfall depths of as little as 5 mm. At rainfall depths of 20 mm, the mandatory limit of 2,000 MPN/100 ml is exceeded half of the time. The likelihood of quickly and easily reducing the bacterial load within urban situations is small, given the lack of retention and treatment facilities for large volumes of storm water. However, microorganisms eventually resettle downstream as well as in the flood storage basin, reducing the well as in the flood storage basin, reducing the water population to background prestorm values. The bacterial population is probably sedimented into the protected environment of the benthal sludge until the next storm flow event. Resuspension increases the probability of intermittent release of microorganisms into the water column, although there will be a dilution effect in the receiving basin. This should help reduce any health risk, although more work is needed to quantify such risks. (See also W91-10612) (Doria-PTT) W91-10632

Levels of motile Aeromonas were monitored in marine recreational waters influenced by sewage discharges north of Valencia (Spain). Microorgadischarges north of Valencia (spain). Microorga-nisms were enumerated by membrane filtration, using mADA/0129 agar. Motile Aeromonas were recovered from all samples. The highest counts of aeromonads (22,200 to 9 million cfu/100 ml) were obtained at Puebla de Farnals, where coliforms were also high, indicating fecal contamination. Th lowest aeromonad counts were detected at Puzol. lowest aeromonau counts were detected at ruzon. Motile Aeromonas and total coliforms exhibited similar cell densities and fluctuations throughout the sampling period. The number of aeromonads exceeded fecal coliforms throughout the year. The exceeded fecal coliforms throughout the year. The population of aeromonads did not exhibit seasonal fluctuations, and was independent of environmental temperatures for most sampling sites. The most frequent species identified were A. caviae, followed by A. hydrophila and A. sobria. Epidemiological studies are needed to determine the specific public health significance of aeromonads in marine recreational waters. (See also W91-10612) (Doria-TTT). W91-10636

PROTECTIVE EFFECT OF GLYCINE BETA-INE ON SURVIVAL OF ESCHERICHIA COLI CELLS IN MARINE ENVIRONMENTS.

Bacteria entering the sea are subjected to an immediate osmotic upshock. Their ability to overcome this shock by means of osmoregulatory systems

#### Sources Of Pollution-Group 5B

influences their survival in marine environments. Glycine betaine (GB) is a very potent osmoprotectant for some bacteria. In Escherichia coli, an increase of external osmolarity induces a strong stimulation of GB uptake. Two distinct GB transstimulation of GB uptake. Two distinct GB transport systems have been characterized in this species: ProP and ProU. The influence of osmoregulation processes on the survival of E. coli in seawater and sediments was investigated using strains harboring proP-lacZ and proU-lacZ gene or operon fusions. The uptake of GB and the expression of both proP and proU were found to be weak in seawater. In marine sediments, proP expression was weak, and GB uptake and proU expression were variable, probably depending on the availability of nutrients. In sediment with high total organic carbon content, GB uptake was very high and proU expression enhanced; cells previously incubated in this sediment showed a higher resistince of the property of the proposition organic caroon content, OB uptake was very mgn and proU expression enhanced; cells previously incubated in this sediment showed a higher resist-ance to decay in seawater. Results show that GB can be accumulated from raw sediments (due to the stimulation of GB uptake and proU gene ex-pression) and that GB accumulation is followed by protective state, allowing cells to survive longer then later starved in seawater. Crowther, and J. Bennet.

Water Science and Technology WSTED4, Vol.

24, No. 2, p 133-136, 1991. 2 fig, 9 ref.

Descriptors: \*Bacterial physiology, \*Bioindicators, \*Escherichia coli, \*Nutrients, \*Survival, \*Suspended solids, Bacteria, Culture media, Glucose, Inorganic compounds, Peptone, Salinity, Seawater, Temperature.

The effect of dissolved nutrients and inorganic suspended solids on Escherichia coli inactivation was examined in laboratory experiments. The study used artificial seawater with dissolved glustudy used artificial seawater with dissolved gui-cose and peptone, laboratory-processed suspended solids, and chemostat steady state E. coli cultures to establish the effect of these parameters on the viability of an E. coli population. Initial E. coli concentration was 5,000/100 ml, the temperatures 5 C and 20 C, the suspended solids concentration range was 0-100mg/L, glucose concentration 1.0 mg/L pertone concentration 9.0 mg/L salinity. range was 0-100mg/L, glucose concentration 1.0 mg/L, speptone concentration 9.0 mg/L, salinity range 27-32%, and the experimental vessels were shielded from light. It has been shown that nutrient-free inorganic suspended solids, at low concentrations, markedly increased the survival of E. coli in seawater. Results of the present study indicate that the presence of dissolved nutrients greatly increases E. coli survival in the absence of suspended solids. However, survival time was greatly reduced at suspended solids concentrations of >5-12 mg/L. thereafter, increasing suspended solids 12 mg/L; thereafter, increasing suspended solids concentration in the range > 12.5-100 mg/L generally resulted in increased survival times. OCCURRENCE OF LEGIONELLA BACTERIA IN COOLING TOWERS IN SOUTH AFRICA.
Council for Scientific and Industrial Research, Pretoria (South Africa). Div. of Water Technology. N. A. Grabow, E. J. Pienaar, and R. Kfir. Water Science and Technology WSTED4, Vol. 24, No. 2, p 149-152, 1991. 2 fig. 7 ref.

Descriptors: \*Cooling towers, \*Legionella, \*Path of pollutants, \*Pathogenic bacteria, \*South Africa, Descriptors: \*Cooling towers, \*Legioneua, rain of pollutants, \*Pathogenic bacteria, \*South Africa, Bacteria, Bacterial analysis, Biocides, Contamination, Immunoassay, Infection, Maintenance, Most probable number test, Public health, Surveys, Water analysis, Water quality standards.

A total of 510 service water samples from cooling towers throughout South Africa were analyzed for the presence of Legionella bacteria. Legionella was detected using an immunolabelling technique based on the most probable number principle. Only

viable bacteria were counted. Legionella bacteria were detected in about 77% of the samples. The majority of the samples were found to have counts between 10 and 500 legionella/ml. In only 4% of the samples were counts higher than 2,200/ml. These results indicate mild levels of contamination These results indicate mild levels of contamination of the majority of the cooling towers. However, it has been reported that such levels can increase drastically within days or weeks under favorable conditions. No guidelines exist for Legionella, and the infectious dose in unknown; therefore, one should aim for the lowest possible counts of legionshould anti for the lowest possible counts of legion-ellae in the maintenance of cooling towers. The fact that about 32% of the samples were found to have no Legionella bacteria indicates that such maintenance can be achieved. The biocide treatmaintenance can be achieved. The blocide treat-ment of 28 cooling towers was found to be highly efficient for Legionella removal. After 3 months' treatment, 67% of the samples tested had no Le-gionella bacteria, while only 10.7% of the samples still had more than 10 bacteria/ml. No correlation still had more than 10 bactera/mi. No correlation could be found between Legionella counts and standard plate counts, suggesting that the use of standard plate counts is impractical and possibly misleading as an indication of Legionella levels in cooling towers. Surfaces within aquatic habitats may be colonized by large quantities of mycobacteria. The growth kinetics and colonization patterns of biofilm myco-bacteria were studied under controlled conditions in two silicone tube systems perfused in two differ-ent periods. In one model system, the density of mycobacterial surface colonization reached a denmycobacterial surface colonization reached a density of more than 100,000 cfu per sq cm after 52 days and of 1 million cfu per sq cm after 10 weeks. The mycobacteria found in the model systems included opportunist pathogens such as Mycobacterium kansasii. Biofilms should therefore be considered for inclusion in the study of health-related environmental mycobacteria. The inactivation rates of the in situ biofilm mycobacteria studied in these extensions with the control of the contro rates of the in situ biofilm mycobacteria studied in these experiments were not or only slightly inferior to those of suspended mycobacterial isolates from the same biofilm. These findings indicate that the general chemical resistance of mycobacteria (which is due to their specific cell wall structure) is not significantly enhanced by their integration into biofilms and protection by bacterial exopolymers. Further studies are needed for statistical confirmation and practical applications of these findings. (See also W91-10612) (Doria-PTT) W91-10642

EPIDEMIOLOGY OF HUMAN CRYPTOSPOR-IDIOSIS AND THE WATER ROUTE OF IN-FECTION.

FECTION.
Public Health Laboratory Service Cryptosporidium Reference Unit, Public Health Laboratory, Glan Clwyd Hospital, Bodelwyddan, Rhyl, Clwyd, LL18 5UJ, Wales.

Cryptosporidium, a protozoan parasite, has emerged during the 1980s as a common cause of gastroenteritis in otherwise healthy subjects and of potentially life-threatening infection in the immun-ocompromised. The parasite, a member of the coc-

cidia, has a complex life cycle resulting in the production of an environmentally hardy stage, the oocyst, excreted in the feces. Cryptosporidium occyst, excreted in the leves. Cryptosportation parvum has a worldwide distribution and infects a wide range of host species including man and livestock. The epidemiology is complex with both direct and indirect routes of transmission. Environinvestock. The epidemiology is compiex with both direct and indirect routes of transmission. Environmental contamination may result in dissemination of infection by water. The widespread practice, even in advanced countries, of disposing of both and animal and human excreta to land, such as by muck and slurry spreading on pasture, may lead to infection directly by aerosol spread during application, or indirectly by contamination of water courses and reservoir feeder streams. Surface waters polluted naturally or by these practices may lead to contamination of water supplies or of food crops during irrigation. Such water may meet current microbiological and other standards. The cocysts are remarkably resistant to most disinfectants including chlorine, but sensitive to ozone. Water may provide the vehicle of infection for sporadic cases and outbreaks, some involving thousands of consumers. The microbiological parameters for covaluating water safety can no longer be relied on to guarantee freedom from risk of infection. (See also W91-10612) (Doria-PTT) W91-10643

OCCURRENCE OF CRYPTOSPORIDIUM SPP. OCCYSTS IN SCOTTISH WATERS, AND THE DEVELOPMENT OF A FLUOROGENIC VIA-BILITY ASSAY FOR INDIVIDUAL CRYPTO-SPORIDIUM OOCYSTS.

Scottish Parasite Diagnostic Lab., Glasgow. H. V. Smith, A. M. Grimason, C. Benton, and J. F. W. Parker.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 169-172, 1991. 3 fig, 1 tab, 6 ref.

Descriptors: \*Cryptosporidium, \*Parasites, \*Pol-lutant identification, \*Protozoa, \*Scotland, \*Water analysis, Dyes, Growth stages, Immunoassay, Morphology, Oocysts, Path of pollutants, Patho-gens, Seasonal variation.

A total of 262 water-related samples were analyzed for the presence of Cryptosporidium spp. oocysts, of which 39,3% were positive, over a 12-month period. Similar data were obtained for their occurrence in samples of both raw and treated water from Scotland, with 40,5% of raw water and 40,1% of treated water being positive. Fewer oocysts were detected in the summer than in the autumn, winter, or spring. In a 12-month survey of water used for abstraction, oocysts were detected at various times throughout the year in both raw and treated water. A series of conventional and fluorogenic dyes was used, in conjunction with a fluorescent labelled monoclonal antibody, in an attempt to assess their potential for improving the identification of oocysts in water-related samples. attempt to assess their potential for improving the identification of occysts in water-related samples. The conventional dyes tested can be used in conjunction with a labelled monoclonal antibody to define both morphometrics and internal structures, thus aiding the identification of individual occysts. Increasing the permeability of oocysts with detergents enhanced the penetration of these dyes into sporozoites. Whereas the fluorescein, auramine, and rhodamine dyes tested highlight sporozoites and rhodamine dyes tested mignight sporozoites predominantly, under certain conditions the occyst wall could also be highlighted. Propidium iodide readily penetrated dead sporozoites and heat-killed oocysts. DAPI, auramine, and rhodamine dyes penetrated oocysts excysted in vitro. (See also W91-10612) (Doria-PTT) W91-10645

Morris, and R. W. A. Girdwood. Water Science and Technology WSTED4, Vol. 24, No. 2, p 179-182, 1991. 1 fig, 2 tab, 12 ref.

Descriptors: "Giardia, "Parasites, "Path of pollut-ants, "Pollutant identification, "Protozoa, "United Kingdom, "Water analysis, Assay, Dyes, Effluents, Potable water, Recreation, Seasonal variation, Wastewater.

Modifications of the existing methods for the isolation of Giardia spp. cysts from water enabled up to 33% of seeded cysts to be recovered. Using this method, 263 environmental samples were analyzed for the presence of cysts, of which 34.4% were positive. All sewage effluents, 85% of recreational waters, 46% of raw potable water samples, and 22% of treated water samples contained cysts (range 0.14-359/L.) Maximum cyst levels were higher in treated compared with untreated waters, but average concentrations of positive samples but average concentrations of positive samples were higher in untreated compared with treated waters. The maximum number of cysts detected in recreational waters was over 10 times that detected in raw water, whereas sewage effluent peak levels were over 1,000 times and 100 times the maximum cyst levels detected in treated and recreational waters, respectively. A higher percentage of positive samples occurred in the summer and autumn in raw water, whereas the levels of cysts in treated waters showed little seasonal variation. A fluoro-genic vital dye assay, which compares favorably with in vitro excystation, was developed, and, using this assay, viable cysts were detected in 33% usang suns assay, vadite cysts were detected in 33% of the positive raw water samples and 42% of the positive treated water samples. The seasonal and geographic distribution of Giardia cysts in wastewater and sludge, and their re-moval by treatment processes, was investigated. Flow-weighted composite samples of raw and

treated wastewaters and sludges were collected monthly for one year from eleven wastewater treatment plants across the United States. Cysts were concentrated by sucrose flotation or by simple centrifugation (direct count) and assayed microscopically. Sucrose flotation counts in raw sewage were extremely variable, producing results ranging from 0.4% to 77.8% of the direct counts. Panging from 0.4% to 77.8% of the direct counts, and using direct counts, the highest geometric mean Giardia cyst concentrations occurred at the California site (3,375 cysts/L), the Florida site (3,087 cysts/L), and the Vermont site (2,040 cysts/L). fornia site (3,375 cysts/L), the Florida site (3,087 cysts/L), and the Vermont site (2,040 cysts/L). The lowest geometric mean Giardia cyst levels were samples from the Pennsylvania site (642 cysts/L), be Tennessee site (762 cysts/L), and the Maryland site (957 cysts/L). Cyst concentrations in raw sewage were highest in late summer, fall, and early winter. Although all raw sewage samples contained cysts, only about one-half of the wastewater treatment plant effluents were positive, with cyst concentrations up to 44 cysts/L. Based on sucrose flotation counts, the concentrations of cysts detected in the sludges ranged from 70 to 30,000 cysts/L. (See also W91-10612) (Author's abstract)

INTERRELATIONS BETWEEN AMOEBAE AND BACTERIA IN THE MOSELLE RIVER, FRANCE.

FRANCE.
Institut Pasteur de Lille, Villeneuve d'Ascq (France). Service des Eaux.
J. M. Delattre, C. Oger, and G. Aprosi.
Water Science and Technology WSTED4, Vol. 24, No. 2, p 193-195, 1991.

Descriptors: \*Amebas, \*Bacteria, \*France, \*Powerplants, \*Temperature effects, \*Water analysis, Chemical analysis, Chlorophyll, Microbiological studies, Moselle River, Pathogens, Rivers, Seasonal variation, Statistical analysis.

The effect of power plant discharges on the presence and abundance of Naegleria, and on other microbiological and chemical parameters, was investigated at 18 sampling stations along the Moselle River (France). Pollution by total bacteria was heavy and uniform. Distribution of thermophilise and the property of the pro was heavy and uniform. Distribution of thermophicia mebae was related statistically (although probably not causally) to fecal pollution. Naegleria distribution appeared to be related to temperature increases, especially downstream of power stations. The dominant species seemed to be N. lovaniensis in early summer and N. australiensis in late summer. Pathogenic N. fowleri were neither frequent nor abundant (maximum 20/100 L); they were found near powerplants, occasionally upstream. Chlorophyll values were uniform (24 mg/cu m). REVIEW OF THE EPIDEMIOLOGY AND DIAGNOSIS OF WATERBORNE VIRAL INFEC-

Institute of Child Health, London (England). Dept. of Virology. W. D. Cubitt.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 197-203, 1991. 1 fig, 46 ref.

Descriptors: \*Epidemiology, \*Human diseases, \*Path of pollutants, \*Public health, \*Viruses, \*Water pollution sources, Chlorination, Clams, Infection, Mollusks, Oysters, Recreation, Reviews, Shellfish, Ships, Swimming, Water conveyance, Water pollution.

A review of advances in the understanding of the A review of advances in the understanding of the significance of viruses as a cause of waterborne infections suggests the importance of problems associated with failures in water supply systems and the hazards of consuming raw or inadequately cooked shellfish. Viruses associated with outbreaks of waterborne infection include Group A and Group B rotaviruses, human caliciviruses, small Group B rotaviruses, numain canciviruses, smail round structured viruses, astroviruses, parvo-like particles, hepatitis A, and poliovirus. Sources of infection have included molluscan shellfish, particularly oysters and clams eaten raw; ice made from fecally polluted water; and water. Between

1976 and 1980, 17 outbreaks of acute nonbacterial gastroenteritis were associated with water. Municipal water supplies were implicated in two out-breaks, semipublic supplies in 7, stored water on cruise ships 2, and recreational swimming water 2. Breakdown of the distribution system is a common cause of outbreaks. Failure to chlorinate swimming pools provides another potential source of infec-tion, and a 3.75 mg/L dose of chlorine sufficient to inactivate polio or human rotavirus has been shown to be insufficient to destroy Norwalk virus. snown to be insurricient to destroy Norwalk Virus. To establish the cause of a waterborne outbreak it is necessary to obtain fecal samples as soon as possible after the onset of symptoms. Acute and convalescent phase samples of serum should be obtained from affected and some asymptomatic individuals. (See also W91-10612) (Doria-PTT) W91-10651

VIROLOGICAL INVESTIGATION OF THE RIVER ELBE.

Medizinische Akademie 'Carl Gustav Carus' Dres-den (German D.R.).

M. Johl, M. L. Kerkmann, U. Kramer, and R. Walter

Water Science and Technology WSTED4, Vol. 24, No. 2, p 205-208, 1991. 3 fig, 1 tab, 2 ref.

Descriptors: \*Elbe River, \*Path of pollutants, \*Pathogens, \*Viruses, \*Water analysis, \*Water pollution sources, Drinking water, Flocculation, Germany, Seasonal variation, Wastewater disposal.

The River Elbe was sampled monthly near Dres-den (Germany), a region where the river, although subject to many domestic and industrial sewage discharges, is used as a source for drinking water. discharges, is used as a source for drinking water.

Samples were concentrated by a two-stage method including aluminum sulfate flocculation. Viral quantification was performed according to the most probably number (MPN) method using F1 cells. Of the samples, 90% were virus positive, with levels ranging from 0.3 MPNCU/L to 52.3 MPNCU/L to 70.00 with an average concentra-MPNCU/L or more, with an average concentra-tion of 7.5 MPNCU/L. This is 12.5 times higher than the level found in the Danube. Local vari-ations of the virus levels were observed. Sampling point 1 (Schmilka) represents the viral contamina-tion coming from Czechoslovakia. Maximum point I (Schmilka) represents the viral contamina-tion coming from Czechoslovakia. Maximum levels were observed at sampling point 3 (Gohlis) just downstream of Dresden, with extensive do-mestic sewage discharges. At this point, virus isola-tion frequency is also highest of all 5 sampling points. Although a well defined seasonal trend in mean viral concentration could not be demonstrated, a trend of increasing virus concentration was observed towards the end of the investigation. VIROLOGICAL QUALITY OF RECREATION-AL WATERS IN THE NETHERLANDS,

Rijksinstituut voor de Volksgezondheid en Milieu-hygiene, Bilthoven (Netherlands). M. van Olphen, H. A. M. de Bruin, A. H. Havelaar, and J. F. Schijven.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 209-212, 1991. 2 fig, 2 tab, 1 ref.

Descriptors: \*Bacteriophage, \*Recreation, \*The Netherlands, \*Viruses, \*Water analysis, \*Water pollution sources, \*Water quality standards, Bacteria, Bioindicators, Enteroviruses, Fecal coliforms, Salmonella, Swimming, Wastewater.

A variety of surface waters in The Netherlands was analyzed for indigenous human enteroviruses in order to evaluate the virological quality of recreational waters for compliance with the mandato-ry European Economic Community (EEC) limit on the absence of enteroviruses in 10-liter samples. The majority of samples that did not exceed the maximum value for fecal coliforms also passed virologically. Eight samples of bathing water (16%) failed to meet the virological requirements of the EEC directive. Only 3 samples out of 51 did not conform to the fecal coliform directive (6%). However, 6 samples that conformed to the fecal coliform standard failed the virus limit. Eleven samples (22%) were positive for salmonellae, of

## Sources Of Pollution—Group 5B

which 8 met the fecal coliform standard. All of the which a first the feed conform standard. All of the enteroviruses isolated were probably from sewage. No enteroviruses could be detected at recreational locations without pollution by untreated sewage or locations without pollution by untreated sewage or effluent discharges from wastewater treatment plants, even though the recreational pressure was high due to warm dry summer weather. The enter-oviruses isolated have yet to be identified. In fresh waters, a better relationship was demonstrated between enteroviruses and FRNA bacteriophages than between enteroviruses and fexal coliforms. Results suggest the utility of these phage as virus models in waters polluted by sewage. (See also W91-10612) (Doria-PTT)

OCCURRENCE OF MALE-SPECIFIC AND SO-MATIC BACTERIOPHAGES IN POLLUTED

MATIC BACTERIOPHAGES IN POLLUTED SOUTH AFRICAN WATERS. Council for Scientific and Industrial Research, Pretoria (South Africa). Div. of Water Technology. R. Kfir, P. Coubrough, and W. O. K. Grabow. Water Science and Technology WSTED4, Vol. 24, No. 2, p 251-254, 1991. 2 fig, 1 tab, 8 ref.

Descriptors: \*Bacteria, \*Bacteriophage, \*Bioindicators, \*South Africa, \*Viruses, \*Water analysis, \*Water quality monitoring, Aquatic environment, Biological treatment, Chlorination, Escherichia coli, Salmonella, Ultraviolet radiation, Wastewater

The occurrence of F' and male-specific coliphages and somatic Salmonella phages in various environ-mental samples from South Africa was studied. mental samples from South Africa was studied. Somatic coliphages outnumbered other bacteriophages in most samples, probably due to the lack of a restriction system in this specific bacterial host. Another explanation for the large number of coliphages obtained is the possible multiplication of the phage in the environmental water samples. Low levels of coliphages were detected using Escherichia coli K12. A marked reduction in malespecific Salmonella phages after biological treatment of the settled sewage can be attributed either ment of the settled sewage can be attributed either to greater sensitivity of these phage to the treatment or to a higher multiplication rate of coli-phages under the same conditions. However, chlorination and dilution in river water resulted in chlorination and dilution in river water resulted in a similar impact on both types of phage with the male-specific phage showing a slightly higher resistance. In dam water, Salmonella phages outnumbered coliphages, possibly due to higher resistance to ultraviolet radiation. In river water, no somatic Salmonella phages were found, and coliphages significantly outnumbered the male-specific Salmonella phages. The low number of male-specific Salmonella phage in river water makes the correlanella phages. The low number of make-specific Salmonella phage in river water makes the correla-tion of these viruses with water difficult. Further comparison studies are needed to verify the corre-lation between male-specific phage and such vi-ruses as rotavirus and hepatitis A. (See also W91-10612) (Doria-PTT) W91-10662

APPLICATION OF MICROBIAL TRACERS IN

APPLICATION OF MICROBIAL TRACERS IN GROUNDWATER STUDIES.
Karlsruhe Univ. (Germany, F.R.). Lehrstuhl fuer Angewandte Geologie.
H. Hotzl, W. Kass, and B. Reichert.
Water Science and Technology WSTED4, Vol. 24, No. 2, p 295-300, 1991. 3 fig, 1 tab, 11 ref.

Descriptors: \*Groundwater movement, \*Groundwater transport, "Microorganisms, "Path of pollutants, "Tracers, Aquifers, Bacteria, Bacteriophage, Filtration, Flow, Karst, Reviews, Sand, Sandstones, Yeasts.

Microbial tracers (bacteria and bacteriophage) were evaluated in several comparative experiments carried out in porous and karst aquifers. Microbial tracers have been used to model subsurface transport of microorganisms, the three main groups used as tracers in groundwater are yeasts, bacteria, and bacteriophage. The most important hydrogeo-logical difference between these groups is the size of the organisms, ranging from about 1,000 nm (yeasts) to about 50 nm (phage). This restricts applicability, especially of the large organisms as general tracers for subsurface flow detection; large

microorganisms can be used only in aquifers with relatively wide openings. This is the case in karst aquifers, where even underground connections of more than 30 km could be marked by microbes. On the other hand, elimination of tracers by filtration in the narrow pores of fine-grained aquifers like sands and sandstones is very efficient and strongly reduces the possibility of migration distance. It is concluded that bacteriophages, because of their concluded that bacteriophages, because of their small size, are the most appropriate microbial tracers. They are completely harmless and applicable under high dilution ratios. By use of different species, they also offer a wide range of tracers for simultaneous experiments. (See also W91-10612) (Doria-PTT) W91-10671

BEHAVIOUR OF PATHOGENIC BACTERIA, PHAGES AND VIRUSES IN GROUNDWATER DURING TRANSPORT AND ADSORPTION.

Tuebingen Univ. (Germany, F.R.). Hygiene Inst. K. Herbold-Paschke, U. Straub, T. Hahn, G.

Teutsch, and K. Botzenhart.
Water Science and Technology WSTED4, Vol.
24, No. 2, p 301-304, 1991. 3 fig, 1 tab, 11 ref.

Descriptors: \*Groundwater transport, \*Path of pollutants, \*Pathogenic bacteria, \*Tracers, \*Viruses, Adsorption, Aquifers, Bacteriophage, Channels, Escherichia coli, Filtration, Germany, Sand, Uranine.

The transport and adsorption behavior of different pathogenic microorganisms was investigated using two kinds of columns filled with quartz sand and two kinds of columns filled with quartz sand and aquifer material. Comparisons were made to uranine tracer. The microorganisms were simian rotavirus SA 11, Escherichia coli, and coliphages T4, MS2, and phi-X174. The breakthrough curve of rotavirus at a filtration rate of 7.8 m/d had a steep main peak with smaller followup peaks; 53% of the viruses injected were adsorbed in the sand. The curve of MS2 phage at a low filtration rate showed a wide distribution, and the peak was delayed by 3 hours. The phage showed a tendency to peak subsequently to or simultaneously to uranine, while the bacteria generally peaked prior to it. More than 50% of the SA 11 rotavirus adsorbed after entering the sand, while only a small percentage of the bacteria and phage adsorbed in the sand. A break-through curve was also generated for E. coli in a inrough curve was also generated for E. Con in a steel channel filled with material from an aquifer near Tubingen (Germany). At a filtration rate of 3.6 m/d, E. coli peaked sharply and dropped sharply after only 2-1/4 hours, while the uranine snarpy arei only 2-1/4 mounts, while the damine tracer remained detectable somewhat longer. Results showed that a change in filtration rate affects the transport behavior of the microorganisms. At reduced filtration rate, microorganisms remained detectable at the column and channel outlets for a much longer time; the percentage of microorganisms adsorbed, however, was no greater than at high filtration rates. FIELD EXPERIMENTS WITH MICROBIOLO-GICAL TRACERS IN A PORE AQUIFER. Tuebingen Univ. (Germany, F.R.). Hygiene Inst. S. Oetzel, W. Kass, T. Hahn, B. Reichert, and K.

Botzenhart.
Water Science and Technology WSTED4, Vol. 24, No. 2, p 305-308, 1991. 4 fig, 1 tab, 5 ref.

Descriptors: \*Bacteria, \*Bacteriophage, \*Groundwater movement, \*Groundwater \*Microorganisms, \*Path of pollutants, Adsorption, Aquifers, Bioindicators, Germany, Serratia, Uranine.

The adsorption and dispersion behavior of Serratia marcescens and the phage phi-X174 were observed in a field near Freiburg (Germany) and compared to that of the tracer uranine. Uranine and phi-X174 to that of the tracer uranine. Uranine and phi-X174 were found to spread with equal velocity 3 h after injection. Serratia and phi-X174 remained concentrated near the injection point, while uranine was distributed to more distant points. The breakthrough curve for uranine shows a relatively flat and uniform drop in concentration. The decrease in concentration of phi-X174 and Serratia was

much more abrupt and irregular. While Serratia was demonstrable to a maximum of only 25 m due to its pronounced adsorption behavior (physicochemical adherence and active adsorption), phi-X174 (physicochemical adsorption but no active adsorption mechanisms) was still detectable to some degree at 100 m. Uranine, which exhibits no sorptive characteristics, was demonstrable in minute quantities even at 400 m. The 6-month persistence of Serratia and phi-X174 under field conditions far exceeded 50 days. This confirms studies showing that the persistence of microorganisms in groundwater aquifers can amount to several months. It is concluded that the transport of a conservative tracer like uranine permits only limited conclusions concerning the possible adsorption and transport characteristics of a microorganisms. On the other hand, the use of microorganisms as indicators of groundwater movement is possible to chemical adherence and active adsorption), phiindicators of groundwater movement is possible to only a limited extent. The major processes governing the persistence and underground transport of viruses and bacteria are reviewed. The simulation of the governing processes is based on the macroscopic mass-conserva-tion equation with the addition of a filter and/or retardation factor and a decay coefficient, representing the natural die-off of the microorganisms. senting the natural die-off of the microorganisms. More advanced concepts try to incorporate growth and decay coefficients together with deposition and declogging factors. None of the reported concepts has yet been validated. Experiments under controlled laboratory conditions are required because of the complexity of natural systems and the pathogenic properties of some of the microorganisms. A laboratory setup is presented in which a great variety of natural conditions can be simulated. This comprises a set of 1-m columns and an 8-m stainless steel flume with 24 sampling ports. The columns are easily filled and conditioned and are therefore used to study the effects of different soil-microorganism combinations under various environmental conditions. Natural underground conditions were simulated in the artificial flume using sand and gravel aquifer material from River sand and gravel aquifer material from River Neckar (Germany) alluvium. Microorganisms studied include the bacteria Escherichia coli, Hafnia alvei, Pseudomonas aeruginosa, Streptococ-cus fecalis; phages T4, MS2, and phi-X174; and poliovirus 1 and rotavirus SA11. The large variety of breakthrough curves and recoveries obtained demonstrate the great uncertainty encountered in microbiological risk assessment. (See also W91-10612) (Doria-PTT)

SPECIES AND GENERA OF ENTEROBACTER-IACEAE IN RIVER NECKAR AND AFTER RIVER BANK FILTRATION AND THEIR RE-SISTANCE PATTERNS TO ANTIBIOTICS AND HEAVY METAL SALTS.

#### Group 5B-Sources Of Pollution

Antibiotics, Aquifers, Bacteria, Cadmium, Chromi-um, Cobalt, Copper, Culturing techniques, Genet-ics, Germany, Mercury, Resistance, Tracers,

Water samples (1,000 L) from the River Neckar (Germany), and observation wells, and a drinking water well were assayed for enterobacters by enrichment in a glucose-peptone medium. The isolated strains were tested for susceptibility to mercury, cadmium, copper, zinc, chromium, and cobalt salts and twelve antibiotics. No difference in susceptibilities to heavy metals was found among the different sample types. The resistance frequencies for tetracycline were generally too low in all observation wells and ranged from 12% to 36% too few resistant strains per well. Of examined strains, 100% were resistant to penicillin G, whereas resistances to all other antibiotics tested were within the range found in clinically isolated strains. Increasing distance from the river, linked with increasing detention periods in the aquifer, had no influence on resistance frequencies. As genes coding for resistance to antibiotics as well as to heavy metals are plasmid-linked in enterobacters, the uniformity of data shows the widespread presence of these plasmids. Enterobacters infiltrating the aquifer with slope water were not distinguished from those infiltrating with river water with respect to their susceptibilities to heavy metals. As this may be caused by the low concentrations of heavy metal salts in the river, further investigations should be undertaken to ascertain if heavy metal susceptibility can be used as a tracer for the origin of enterobacters in the aquifer. ## BDELLOVIBRIO SP.: A PREDATOR UNDER GROUNDWATER CONDITIONS. A SHORT COMMUNICATION.

Bundesgesundheitsamt, Langen (Germany, F.R.). Inst. fuer Wasser-, Boden- und Lufthygiene. Z. Filip, P. Schmelz, and R. Smed-Hildman Water Science and Technology WSTED4, Vol. 24, No. 2, p 321-324, 1991. 3 fig, 5 ref.

Descriptors: \*Bacteria. \*Bdellovibrio. \*Biocontrol. Peaciptors: Pacceria, Policioritori, Pacceritoris, Pacceri

The role of Bdellovibrio sp. in affecting the development of Gram-negative bacteria under natural conditions is not yet completely understood. No predatory activity was observed in studies of groundwater samples from a deep pristine aquifer near Langen (Germany). Temperature and pH may play a role as limiting factors. Their ambient values were 10 C and 6.07, respectively. In laboratory experiments using a collection strain of B. bacteriovorus and a wild type from sewage, appreciable numbers of plaques appeared at a minimum temperature of 18 C. The optimum temperature at which more than 100 plaques were counted was 26 C and 30 C. At pH values lower than 6 no plaques c and 30 C. At pri values lower than 6 no plaques were formed, but more than 100 plaques were observed at pH 7, 8, and 9. Different growth stages were identified from the individual plaques using a transmission electron microscope. It is concluded that Bdellovibrio sp. probably does not play a role in the control of populations of Gram-negative bacteris in groundwater having a explaint. bacteria in groundwater having an ambient temperoacteria in groundwater naving an amoient temper-ature of 10 C. However, this presumption needs to be studied, especially in polluted aquifers and in the presence of solid particles from groundwater aquifers; these factors may greatly influence the behavior of both predator and prey. Descriptors: \*Industrial wastewater, \*Path of pollutants, \*Pharmaceutical wastes, \*Volatile organic compounds, \*Water pollution effects, Aquatic environment, Aquatic life, Carcinogens, Environmental effects, Public health.

The Industrial Technology Division (ITD) of the US EPA conducted a study of the pharmaceutical manufacturing industry as a result of findings from the Domestic Sewage Study (DSS) and from concern for the potential discharge of toxic and hazardous pollutants from this industry. The study consisted of the following three interrelated but independent undertakings: a technical support study; an economic impact analysis; and an environmental impact analysis. The technical study confirmed that the pharmaceutical manufacturing industry discharges significant quantities of potential in the pharmaceutical manufacturing industry discharges significant quantities of potential in the pharmaceutical manufacturing industry discharges significant quantities of potential in the pharmaceutical manufacturing industry discharges significant quantities of potential in the pharmaceutical manufacturing industry discharges significant quantities of potential in the pharmaceutical manufacturing industry discharges significant quantities of potential in the pharmaceutical manufacturing industry discharges significant quantities of potential in the pharmaceutical manufacturing industry discharges significant quantities of potential industry discharges significant quan industry discharges significant quantities of poten-tially hazardous compounds (especially priority and nonconventional volatile organic compounds and nonconventional volatile organic compounds (VOCs) in raw wastewater. Based on information obtained in the screening and verification sampling program, EPA estimates that 4.7 million lb/yr of priority pollutant VOCs are discharged in the industry's raw wastewater. Sections VIII, X, and XI present the economic impact analysis. The environmental impact study is presented in Section XII. Water quality impacts were projected for 22. ronmental impact study is presented in Section XII. Water quality impacts were projected for 22 direct and 28 indirect discharging plants. Fifteen VOCs were evaluated for direct dischargers, eight of which (all known or suspected carcinogens) were projected to exceed human health criteria in 86% of the stream segments. None of the VOCs evaluated were projected to exceed aquatic life criteria or toxic effect levels. The effects of 28 indirect discharging plants were also evaluated. Twenty-one VOCs were evaluated and six (all known or suspected carcinogens) were projected to exceed human health criteria for carcinogens in 60% of the streams receiving discharges from the publicly owned treatment works (POTWs) to which the plants discharge. No volatile pollutants were projected to exceed aquatic life criteria or toxic effect levels. The impacts by VOCs, as monitored on five streams receiving direct discharges from pharmaceutical plants and on six streams receiving discharges from facilities discharging to POTWs were evaluated. Nine of the 15 pollutants evaluated were detected in four streams receiving direct discharges. Two of the pollutants exceeded human health criteria in three of the streams. Eight of the 21 pollutants evaluated were detected in four streams. Eight of the 21 pollutants evaluated were detected in four streams receiving indirect discharges. Three of the pollutants exceeded human health criteria in three of the streams. (Lantz-PTT) W91-10710

Descriptors: \*Cleanup, \*Fate of pollutants, \*Hazardous wastes, \*Path of pollutants, \*Site remediates ation, \*Soil contamination, \*Volatile organic comation, "Soil contamination, "Volatile organic com-pounds, Acrylonitrile, Benzenes, Bioaccumulation, Biodegradation, Chloroform, Dichlorobutene, Furans, Naphthalenes, Organic compounds, Phys-icochemical analysis, Sorption, Toluene, Trichloropropane

Selected hazardous organics, primarily volatiles and semivolatiles, were evaluated for toxicity to soil microorganisms, sorption to soil, degradation, and potential for bioaccumulation in terrestrial plants and animals. The chemicals included in the study were acrylonitrile, furan, methyl ethyl ketone, tetrahydrofuran, benzene, toluene, 1,2dichloroethane, p-xylene, chlorobenzene, chloro-form, nitrobenzene, trans-1,4-dichloroethane, cis-1,4-dichloro-2-butene, 1,2-dichlorobenzene, 1,2,3-trichloropropane, carbon tetrachloride, 2-chloron-aphthalene, benzidine, ethylene dibromide, 3,3-di-methylbenzidine, 1,2,4,5-tetrachlorobenzene, 3,3dichlorobenzidine, methylpyrilene, and hexachloro-benzene. Sorption partition coefficiencies based on oenzene. Sorption partition certificate osaet on soil organic matter were high for 2-chloronaphthalene (4.65) and hexachlorobenzene (4.59); were moderate for toluene (2.19), p-xylene (2.60), chlorobenzene (2.33), cis-1,4-dichloro-2-butene (2.33), 1,2-dichlorobenzene (2.99), carbon tetrachloride (2.06), nitrobenzene (1.99), 1,2,3-trichloropropane (1.92) and 1,2,4,5-tetrachlorobenzene (2.79); and (1.92) and 1,2,4,5-tetrachlorobenzene (2.79); and low for the remaining compounds. Those chemicals with the longest half-lives in soil were nitrobenzene, hexachlorobenzene, 1,2,4,5-tetrachlorobenzene, and 2-chloronaphthalene, whereas those rapidly nonrecoverable by solvent extraction were p-xylene, chlorobenzene, chloroform, and cis-1,4-dichlorobenzene. Evaluation of all 24 chemicals dichlorobenzene. Evaluation of all 24 chemicals for bioaccumulation potential based on physicochemical properties implicated only 1,2,4,5-tetrachlorobenzene and hexachlorobenzene tot be of high concern. Linear correlations for physicochemical parameters with chemical effects on soil respiration and degradation parameters were poor for the complete data set. However, they were quite good for a subset of benzene and its chloro, and alkyl-derivatives. (Lantz-PTT) W91-10712

ACID-BASE STATUS OF PENNSYLVANIA STREAMS: RESULTS FROM THE NATIONAL STREAM SURVEY.

SIREAM SURVEY,
Virginia Univ., Charlottesville.
K. N. Eshleman, P. R. Kaufmann, and A. T.
Herlihy.
Available from the National Technical Information
Service, Springfield, VA 22161, as PB90-134313.
Price codes: A03 in paper copy, A01 in microfiche.
Report No. EPA/600/D-89/224, 1989. 10p, 1 fig, 1
tab, 11 ref.

Descriptors: \*Acid rain, \*Acid streams, \*Acidifica-tion, \*Hydrogen ion concentration, \*Path of pol-lutants, \*Pennsylvania, Acid neutralizing capacity, Acidity, Water pollution effects, Water quality.

The National Stream Survey, (NSS) conducted by the EPA in the spring of 1986, sampled 82 stream reaches within the state of Pennsylvania, represent-ing a target population of 9900 stream reaches that are potentially sensitive to acidification. After ex-cluding streams that were acidified by acid mine drainage, an estimated 9% of the reaches were chronically acidic during spring baseflow at the upstream end, while less than 1% of the stream reaches were acidic at their downstream end. Comparable percentages of streams with an acid neutralizing capacity (ANC) between 0 and 50 microeq/L were also identified, with the majority microeq/L were also identified, with the majority of these streams found in the Appalachian Plateau. Almost all of the chronically acidic streams in the state are small (<20 sq km), upland headwater streams draining watersheds that are more than 95% forested. Population estimates of the percentages of streams with an ANC < 200 microeq/L. agree favorably with an Arc V agree favorably with estimates by the Pennsylvania Fish Commission for managed and unmanaged stream sections of the state. Service, Springfield, VA. 22161, as DE88-010377.

Price codes: A05 in paper copy, A01 in microfiche.
Report No. DP-1739-1, October 1987. 68p, 14 fig.,
7 tab, 60 ref. DOE Contract DE-AC09-6SR00001.

Descriptors: \*Cooling water, \*Path of pollutants, \*Savannah River Plant, \*Thermal pollution, Beaver Dam Creek, Flow pattern, Four Mile Creek, Nuclear powerplants, Nuclear reactors, Par Pond, Steel Creek, Three Runs Creek.

The Savannah River Plant (SRP) was acquired by the US Government in the early 1950s to construct a facility for production of nuclear materials for a facility for production of nuclear materials to the United States weapons program. Most major nuclear material production related facilities were completed and operational by 1954. These facilities included a fuel fabrication facility, five production reactors, two chemical separations facilities to

remove and purify the required radioisotopes, a remove and purify the required radioisotopes, a heavy water moderator production facility, and a coal-fired electricity/steam generation facility. Ad-ministrative and support facilities were also con-structed. Initially, all five production reactors, the coal-fired power plant, and the heavy water facili-ty were cooled in a once-through mode using water pumped through three intake structures lo-cated on the Savannah River. Both the volume of the water pumped and the temperature of the discharged effluent tended to increase through the 1950s as reactor power levels were increased. At 1950s as reactor power levels were increased. At peak power levels, SRP reactors discharge approximately 11 cu m/sec of cooling water at 70 C to 75 C. Four of the five major stream systems on io 75 C. Four of the five major stream systems on the SRP have received reactor effluents. Beaver Dam Creek, a lesser drainage system, has received cooling water releases of a smaller magnitude than those creeks associated with reactor operations (Four Mile Creek, Pen Branch, Steel Creek, Lower Three Runs Creek). Only Upper Three Runs Creek has not received cooling water effluent. Four SRP streams that have received cooling water releases drain into the SRP Savannah River swamp, a 3,800 ha riverine swamp forest bordering the Savannah River and contained within the SRP boundaries. Flows from Upper Three Runs and boundaries. Flows from Upper Three Runs and Lower Three Runs Creeks discharge directly into the Savannah River, but these streams have relatively little swamp forest development near the creek mouths. REMEDIAL INVESTIGATION OF THE HIGH EXPLOSIVES BURN PIT FACILITY, BUILD-ING 829 COMPLEX, LAWRENCE LIVER-MORE NATIONAL LABORATORY SITE 300. Lawrence Livermore National Lab., CA. Environ-

Lawrence Livermore National Lab., C.A. Environ-mental Restoration Div. C. P. Webster-Scholten, and N. B. Crow. Available from the National Technical Information Service, Springfield, VA. 22161, as DE89-017741. Price codes: A04 in paper copy, A01 in microfiche. Report No. UCID--21692, August 1989.

Descriptors: \*Explosives, \*Groundwater pollution, \*Lawrence Livermore National Laboratory, \*Path of pollutants, \*Water pollution sources, Geohydrology, Infiltration, Monitoring wells, Piezometers, Trichloroethene, Volatile organic compounds.

To assess any impact on the environment resulting from operations at the High Explosives (HE) Burn Pits at Lawrence Livermore National Laboratory (LLNL) Site 300, the soil, rock, and groundwater beneath the burn pit facility, were evaluated. Between November 16, 1986, and January 12, 1987, eight exploratory holes were drilled; one was converted to a monitor well, and another was converted to a piezometer. Seven holes were drilled, geologically logged, and sampled to determine the concentration and extent of substances that may have infiltrated to the subsurface from the burn pits. The eighth hole was completed as a monitor well but was not sampled, and no detailed log was prepared. Electric logging was performed in one exploratory hole to further evaluate the geologic conditions. The evaluation of the HE Burn Pit facility showed that levels of HE compounds in facility showed that levels of HE compounds in the underlying soil and rocks are generally low, with concentrations higher at the surface, decreas-ing with depth. Some aberrations have been re-ported; e.g., the increase in HE concentrations between 95 and 100 ft in hole 829-03 in a weath-rerd-appearing zone with abundant fractures (pos-sibly resulting from earth movement). With the excention of one surficial sample in one exploratoexception of one surficial sample in one exploratory hole, all explosives concentrations in soils are significantly below the designated levels. Volatile organic compounds (VOCs) in soil and rocks have organic compounds (VOCs) in soil and closs have been reported only beneath pits 2 and 3 and at low concentrations. Concentrations of trichloroethene (TCE) up to 5.4 microgm/L in water from well W-829-08 are slightly above the State Action

Level. Further analyses of water samples will provide information with which a trend analysis may be made, but it currently appears that the concen-trations of TCE in groundwater may be decreas-ing. Because the burn pits are regulated under the authority of the Resource Conservation and Re-covery Act (RCRA), a RCRA closure is required for the HE Burn Pit Facility. (Lantz-PTT) W91-10731

STATUS OF GROUND WATER IN THE 1100

Westinghouse Hanford Co., Richland, WA.

A. G. Law.

A. U. Law. Available from the National Technical Information Service, Springfield, VA. 22161, as DE89-016119. Price codes: A03 in paper copy, A01 in microfiche. Report No. WHC-MR-0034, July 1989. 25p. DOE Contract DE-AC08-87RL10930.

Descriptors: \*Data collections, \*Groundwater quality, \*Hanford Site, \*Monitoring, \*Washington, Drinking water, Maximum contaminant level, Monitoring wells, Water quality, Water quality

The groundwater in the 1100 Area of the Hanford Site, Richland, WA is monitored as a precautionary measure since the City of Richland's recharge and well field site is downgradient from the US Department of Energy (DOE) past practice, non-radioactive disposal sites. It is believed that there is insufficient desires from the US radioactive disposal sites. It is onleved that there is insufficient driving force to move contaminants down to the water table, and modeling suggests that the well field is operated in such a manner that movement into the well field is unlikely. Monitoring of five wells installed in late 1988 is being conducted to provide additional assurance on the safety of the groundwater for use by residents of Richland. The three wells near the well field are sampled monthly and analyses are performed for several constituents deemed to be indicative of potential contaminants from DOE facilities. All several constituents deemed to be indicative of potential contaminants from DOE facilities. All five wells are sampled quarterly with analyses conducted for a lengthy list of constituents. Results of the analyses indicate that the groundwater meets drinking water standards. The results of the monitoring to date comprise the majority of this document. The first section is a map of the 1100 Area showing the location of the five new wells. Section 2 is a listing of the analytical results from the monthly sampling of the three wells near the well field. Section 3 is a listing of all results for routine monitoring of the wells since the work was initiated in November 1988. This listing contains the detection limit and the drinking water standard or maximum contaminant level, where appropriate, of each constituent. In reviewing the data, it was observed that the concentration of nitrate, although one-half the drinking water standard, was higher in Well 699-S43-E12 near the Purchasing building vis-a-vis the other wells. The reason for apparent anomaly is to be investigated as more data become available. (Lantz-PTT)

PRELIMINARY DATA SUMMARY FOR THE HOSPITALS POINT SOURCE CATEGORY.

Environmental Protection Agency, Washington, DC. Office of Water Regulations and Standards.

Available from the National Technical Information Service, Springfield, VA. 22161, as PB90-126459. Price codes: A05 in paper copy, A01 in microfiche. Report No. EPA 440/1-89/060-n, September 1989. 76p, 2 fig, 14 tab, 15 ref, 2 append.

Descriptors: \*Data collections, \*Hospitals, \*Water pollution sources, Hazardous wastes, Pollutant identification, Waste management.

This is one of a series of Preliminary Data Summa-ries prepared by the Office of Water Regulations and Standards of the US EPA. The Summaries and Standards of the US EPA. The Summaries contain engineering, economic and environmental data that pertain to questions about whether the industrial facilities in various industries discharge pollutants in their wastewaters, and whether the EPA should pursue regulations to control such discharges. This document summarizes the most

#### Group 5B-Sources Of Pollution

current information available regarding the dis-charge of wastewater and solid wastes containing priority and hazardous non-priority pollutants by hospitals. The objectives of this document are to: (1) provide a technical basis for determining (1) provide a technical basis for determining whether additional national regulations should be developed pursuant too the Clean Water Act (CWA), and (2) make available preliminary information regarding the discharge of priority and hazardous non-priority pollutants by the hospital industry. The hospital industry profile is presented in Section 2.0. Section 3.0 characterizes hospital wastewater in terms of the presence of priority and hazardous non-priority pollutants and provides ad-ditional information on these and other pollutant discharges from hospitals. Various waste management practices and control and treatment technologies are described in Section 4.0. Environmental and economic impact analyses were not performed as part of this study and, consequently no such analyses are discussed in this document. (Lantz-PTT) W91-10738

Descriptors: \*Data collections, \*Pesticides, \*Surveys, \*Water pollution sources, Industrial production, Industrial wastes.

This is one of a series of Preliminary Data Summa-ries prepared by the Office of Water Regulations and Standards of the US EPA. The Summaries and standards of the US EA. The summaries contain engineering, economic and environmental data that pertain to questions about whether the industrial facilities in various industries discharge pollutants in their wastewaters, and whether the pollutants in their wastewaters, and wnemer me EPA should pursue regulations to control such discharges. This Preliminary Data Summary for the Pesticide Chemicals Point Source category consists of: (1) early findings from the EPA Census of Pesticides; and (2) EPA estimates of pollutant of Pesticides; and (2) EPA estimates of pollutant discharges (loads) for pesticide manufacturers and pesticide formulators and packagers (PFPs). The EPA designed the 'Pesticide Manufacturing Facility Census' for 1986 to collect information on production, wastewater generation and treatment, and financial data from pesticide manufacturing plants. The Census requested information relating to the production of approximately 300 pesticide activing redients (Als), known as 'in-scope Als.' Two hundred forty-two copies of the technical portion of the questionnaire were distributed to the pesticide chemicals industry in the Summer of 1988. Based upon the returned questionnaires: 92 are manufacturers of in-scope Als; but not manufacturers of out-of-scope Als, but not manufacturers of in-scope Als; 80 are Pesticide Formulators/Packagers (PFPs), but not manufacturers; 34 are neither ers (PFPs), but not manufacturers; 34 are neither anufacturers nor PFPs; and, 26 are closed. The 92 manufacturers produce 160 in-scope Als. Of those 92 plants: 35 are direct dischargers; 36 are indirect dischargers; and, 21 are no-discharge plants. (Lantz-PTT) W91-10739

The ARCHIMEDES IIa was an experiment on oil slick detection conducted over the North Sea. Data was obtained using the experimental airborne synthetic aperture radar (SAR) system-E-SAR. The system was part of the research program at the Institute for Radio Frequency Technology of the German Aerospace Research Establishment. During the experiment carried out on 21. Amont. During the experiment carried out on 21 April 1988, the system was operated in L-band at 1.29 GHz, and results were obtained concerning an oil of 5 cu m of crude oil. The data showed that slick of 5 cu m of crude oil. The data showed that a SAR is suitable for oil spill detection on the sea surface, and demonstrated the capability of the L-band E-SAR system, even with a very low transmitted peak power of 50 W, at altitudes of up to 1000 M above ground. It was also shown to be possible to discriminate between the oil and sea surface. If there had been simultaneous radiometer measurements, a thickness distribution within the oil slick could also have been derived. Finally, it was found that the data could distinguish between was found that the that could distinguish between different types of oil spills or biogenic films, by evaluating the intensity histograms of the SAR image data. URBAN STORM-INDUCED DISCHARGE IM-

Environmental Protection Agency, Edison, NJ. Storm and Combined Sewer Technology Branch. R. Field, and R. E. Pitt.

Available from the National Technical Information Service, Springfield, VA. 22161, as PB90-112566. Price codes: A04 in paper copy, A01 in microfiche. Report No. EPA/600/D-89/130, 1989. 7p, 26 ref.

Descriptors: \*Land use, \*Path of pollutants, \*Storm runoff, \*Urban runoff, \*Water pollution edfects, \*Water pollution sources, Aquatic life, Bellevue, California, Coyote Creek, Fishkill, Sediment transport, Toxicity, Urbanization, Washington, Water chemistry.

The effects of storm-induced discharges on receiving water aquatic organisms or other beneficial uses is very site specific. Different land developmeet practices may create substantially different runoff flows. Different rain patterns cause different particulate washoff, transport and dilution condi-tions. Local attitudes also define specific beneficial uses and desired controls. There is also a wide variety of water transuses and desired controls. There is also a wide variety of water types receiving urban runoff, and these waters all have watersheds that are urbanized to various degrees. Therefore, it is not surprising that urban runoff effects are also quite variable and site specific. Attempts to identify urban runoff problems using available data have not been con-clusive because of differences in the sampling pro-cedures and the common practice of prodling data cedures and the common practice of pooling data from various sites, or conditions. It is, therefore, necessary to carefully design comprehensive, long-term studies to investigate urban runoff problems on a site specific basis. Sediment transport, deposition, and chemistry play key roles in urban receivations. on a site specific oasis. Sediment transport, deposi-tion, and chemistry play key roles in urban receiv-ing waters and need additional research. Receiving water aquatic biological conditions, especially compared to unaffected receiving waters, should be studied to support laboratory bioassays and literature information. The two West Coast studies summarized in this paper both found significant aquatic life beneficial use impairments in urban creeks, but the possible causes were quite different. The Coyote Creek, California study found major accumulations of toxic sediments in the urban accumulations of toxic secuments in the urban reaches of the creek, while the Bellevue, Washing-ton study found very little toxic material in the sediments. The Bellevue urban creek had a very large carrying capacity for sediment and high flow

rates which apparently flushed the toxic sediments through the creek and into Lake Washington. Fish kills were observed in Bellevue, but they were associated with illegal storm drain discharges during dry weather. The long-term aquatic life effects of urban runoff are probably more important than short-term effects associated with specific versits. The long-term effects are probably related. tant than short-term effects associated with specific venents. The long-term effects are probably related to the deposition and resuspension of toxic sediments, or the inability of the aquatic organisms to adjust to repeated exposures to high concentrations of toxic materials or high flow rates. Long-term effects may only be expressed at great distances downstream from discharge locations, or in accumulating areas (such as lakes). (Lantz-PTT) W91-10745

SOIL VAPOR SURVEY AT THE LLNL SITE 300 GENERAL SERVICES AREA, ADJACENT PORTIONS OF THE CONNOLLY AND GALLO 6 AREA.

Weiss Associates, Oakland, CA. S. Vonder Haar, J. Pavletich, W. McIlvride, and M. Taffet.

Descriptors: \*Groundwater pollution, \*Lawrence Livermore National Laboratory, \*Path of pollut-ants, \*Soil contamination, \*Soil vapor, \*Trichlor-oethylene, \*Water pollution sources, Dichloroeth-ene, Diffusion, Monitoring, Monitoring wells, Te-tanh Lorecthylene, Trichloroeth-gue trachloroethylene. Trichloroethane

During October through December, 1988, a soil vapor survey was conducted at the Lawrence Livermore National Laboratory Site 300 General Services Area (GSA), adjacent portions of the Connolly and Gallo Ranches, and at the Site 300 Landfill Pit 6 area. The purpose of the investigation was to aid in identifying the sources and the extent of trichloroethylene (TCE) previously found in groundwater and soil at, or near, these sites. Using a soil vapor probe, samples were collected at 133 locations from depths of 2 to 15 ft below the surface. TCE concentrations detected in below the surface. TCE concentrations detected in the soil vapor ranged from a high of 628 parts per million (ppm) to a low of not detected (ND) at < 0.001 to 0.005 ppm. The highest concentration was found next to monitor well W-7F, near a decommissioned drywell (sump) at the southern boundary of the GSA. Several locations exhibited ND of the higher concentrations of TCE (> 30 ppm) detected in the soil vapor at five sample points are attributable to TCE sources in unsaturated soil. The lower concentrations (< 5 ppm) may reflect either low concentration TCE sources in unsaturated soil and/or diffusion of TCE upward from contaminated groundwater. (Lantz-PTT) W91-10747

#### Sources Of Pollution—Group 5B

47 tab, 16 ref, 4 append. DOE Contract DE-AC06-76RLO 1830.

Descriptors: \*Columbia River, \*Dredging effects, \*Dredging wastes, \*Environmental impact, \*Oregon, \*Water pollution sources, Amphipods, Chemical analysis, DDT, Dredging, Estuaries, Path of pollutants, Pollutant identification, Polychaetes, Sediment contamination, Water resources

The state of Oregon plans to develop a former ship supply and storage site near Tongue Point, Oregon, for commercial shipping, requiring dredging of the adjacent waterway to the Columbia River 40-foot channel to admit commercial vessels. Bioassays were conducted which would provide technical data for an evaluation of the potential environmental impact of ocean disposal of the dredged material. These tests revealed elevated concentrations of some contaminants in the Tongue Point sediment. All solid-phase bioassays (conducted on clams, polychaetes and amphipods) (conducted on clams, polychaetes and amphipods) < 10% mortality in both reference and control sediments, which makes all tests valid. The bioas-says under static and flow-through conditions resulted in no statistically significant difference in survival among treatments for three of the four test species. Only one test (R. abronius, static) had species. Only one test (R. abronus, static) had survival in test sediments significantly different from controls. In that test > 10% of the amphipods died in the test sediment; however, survival ranged from 60 to 95% among the replicates of the two composites. This indicates a possible patchiness to the sediment toxicity even though the composites appeared homogeneous A class disposal of posites appeared homogeneous. Actual disposal of Tongue Point sediment in the ocean will probably result in dilution of contaminants by flowing sea-water during and after its descent to the sea floor, water during an after its descent or the sea froot, thereby minimizing acutely toxic effects. A significant enhancement of 4,4'-DDD, a degradation product of DDT, was seen in the issues of clams at an average concentration of 8.0 micrograms/Kg (wet weight). Allowable limits for interstate commerce are 5000 micrograms/Kg (wet weight), or a factor of 625-fold the concentration measured in the clams. No other chemicals were bioaccumulated. (Lantz-PTT) W91-10753

GROUND-WATER FLOW AND SOLUTE MOVEMENT TO DRAIN LATERALS, WEST-ERN SAN JOAQUIN VALLEY, CALIFORNIA. I. GEOCHEMICAL ASSESSMENT.

Geological Survey, Sacramento, CA. S. J. Deverel, and J. L. Fio. Available from the US Geological Survey, Books and Open-File Reports Section, Box 25425, Feder-al Center, Denver, Co. 80225-0425. Open-File Report 90-136, 1990. 23p, 15 fig, 25 ref.

Descriptors: \*California, \*Geochemistry, \*Geohydrology, \*Groundwater movement, \*Path of pollutants, \*San Joaquin Valley, \*Selenium, \*Solute transport, Drainage, Drainage systems, Flow profiles, Groundwater irrigation, Groundwater recharge, Mixing.

A study was undertaken to quantitatively evaluate the hydrologic processes affecting the chemical and isotopic composition of drain lateral water from an agricultural field in the western San Joaquin Valley, California. Results from chemical and isotopic analysis of the samples, and analysis of hydraulic head data and drain lateral flow data, elucidate the process of mixing of deep and shallow groundwater entering the drain laterals. The deep groundwater was subject to partial evaporation prior to drainage system installation and has been displaced downward (at depths > 6 meters) been displaced downward (at depths > 6 meters) in the groundwater system. This groundwater is flowing toward the drain laterals. The percentage of deep, isotopically enriched groundwater enter-

ing the drain laterals varies with time and between drain laterals. The percentage of the total drain lateral flow, which is deep groundwater flow, is about 30% for the shallow drain lateral (1.8 meters about 30% for the shallow drain lateral (1.8 meters below land surface) and 60% for the deep drain lateral (2.7 meters below land surface). During irrigation, these percentages decrease to 0 and 30% for the shallow and deep drain laterals. Selenium loads in the drain laterals vary with time and between drain laterals. The selenium load for the shallow drain lateral (8 kg) during 1 year is 21% of the load for the deep drain lateral (332 kg) because it collects less deep, high selenium groundwater and does not flow continuously. Although selenium concentrations in the drain lateral water decreased during irrigation, selenium loads inselenium concentrations in the drain lateral water decreased during irrigation, selenium loads increased substantially during a preplant irrigation because of increased flow into the drain laterals. The selenium loads during 8 days of irrigation represented a substantial percentage (25% for the shallow drain lateral and 11% for the deep drain lateral) of the total selenium load for 1 year. (See also W91-10769) (Author's abstract)

GROUND-WATER FLOW AND SOLUTE MOVEMENT TO DRAIN LATERALS, WEST-ERN SAN JOAQUIN VALLEY, CALIFORNIA. II. QUANTITATIVE HYDROLOGIC ASSESSMENT.

Descriptors: \*Drainage, \*Geohydrology, \*Groundwater movement, \*Path of pollutants, \*San Joaquin Valley, \*Selenium, \*Solute transport, California, Groundwater irrigation, Groundwater recharge, Hydrologic models, Irrigation, Models tudies, Simulation analysis, Surface-groundwater

Groundwater flow modeling was used for the estimation of groundwater flow paths and travel times to quantitatively assess the hydrologic processes to quantitatively assess the hydrologic processes affecting groundwater and solute movement to drain laterals. Modeling results were used to calculate the depth distribution of groundwater flowing into drain laterals at 1.8 meters (drain lateral 1) and 2.7 meters (drain lateral 2) below the land surface. These simulations indicated that under nonitrigations of the desired of the control of the These simulations indicated that under nonirrigated conditions, about 89% of the flow in drain lateral 2 was from groundwater originating at depths > 6 m below the land surface. Deep groundwater was found to have higher selenium concentrations than shallow groundwater. Simulation of irrigated conditions indicates that as recharge increases, the proportion of deep groundwater entering the drain laterals decreases. Groundwater flow modeling also was used to estimate selenium loads in drain laterals for varying drain lateral flow rates. Simulated loads were in general agreement with measured loads and increase with increasing drain lateral flow. Simulations further indicated that groundwater containing high selenium concentrations probably will ing high selenium concentrations probably will continue to enter drain lateral 2 for more than 8 years. PERMEABILITY OF SOILS WITH ORGANIC

Arizona Univ., Tucson. Dept. of Civil Engineering and Engineering Mechanics. M. Budhu, R. F. Giese, G. Campbell, and L.

Baumgrass. Canadian Geotechnical Journal CGJOAH, Vol. 28, No. 1, p 140-147, February 1991. 5 fig, 2 tab, 16

Descriptors: \*Leachates, \*Oil pollution, \*Organic compounds, \*Path of pollutants, \*Permeability, \*Soil properties, \*Soil types, Clays, Correlation analysis, Dielectric constant, Fluid flow, Illite, Kaolinite, Montmorillonite, Permeameters, Physical properties, Soil mechanics

Permeability measurements, using a consolido-meter, were made for kaolinite, montmorillonite, and a clay-rich soil (the Lockport clay) with a variety of organic liquids and water as permeants. These data, along with selected values from the literature, were used to evaluate several theories literature, were used to evaluate several theories that have been proposed as explanations for the general observation that permeabilities of clay soils with organic fluids as the permeants are higher than with water as the permeant. Of the several obvious differences in physical properties between water and organic liquids (e.g., dielectric constant, viscosity, dipole moment, specific gravity, and surface tension), only the dielectric constant provided a consistent correlation with the permeabilities a consistent correlation with the permeabilities a consistent contention with the permeabilities for the or-ganic chemicals used can be predicted using the measured permeability for the soil with water as the permeant and the dielectric constant of the organic by way of an exponential equation. For mixtures of acetone-water and methanol-water, the permeabilities did not vary linearly with the com-position. Rather, the permeabilities remained close to values for pure water until approximately 70% (by volume) of the fluid was organic. (Author's abstract) W91-10783

Ground Water Monitoring Review GWMRDU, Vol. 11, No. 2, p 93-100, Spring 1991. 11 fig, 14 ref.

Descriptors: "Gasoline, "Groundwater pollution, "Groundwater recharge, "Path of pollutants, "Solute transport, Benzene, Correlation analysis, Infiltration, Oil spills, Organic compounds, Rainfall, Sampling, Soil gases, Toluene, Unconfined aquifers, Xylenes.

At an aviation gasoline spill site in Traverse City, Michigan, historical records indicate a positive correlation between significant rainfall events and increased concentrations of slightly soluble organic compounds in the monitoring wells of the site. To investigate the recharge effect on groundwater quality due to infiltrating water percolating past residual oil and into the saturated zone, an in situ residual oil and into the saturated zone, an in situ infiltration experiment was performed at the site. Sampling cones were set at various depths below a circular test area, 13 feet (4 meters) in diameter. Rainfall was simulated by sprinkling the test area at a rate sufficiently low to prevent runoff. The response of the soil-gas and groundwater quality were monitored during the recharge and drainage periods, which resulted from the sprinkling. Infiltrated water was determined to have transported organic constituents of the residual oil, specifically benzene, toluene, ethylbenzene, and ortho-xylene (BTEX), into the groundwater beneath the water table, elevating the aqueous concentrations of these constituents in the saturated zone. Soil-gas concenidual oil and into the saturated zone, an in situ table, elevating the aqueous concentrations of these constituents in the saturated zone. Soil-gas concentrations of the organic compounds in the unsaturated zone increased with depth and time after the commencement of infiltration. Reaeration of the unconfined aquifer via the infiltrated water was observed. Water quality measurements were directly coupled to recharge events for the sandy type of aquifer with an overlying oil phase. (Author's abstract) W01-10703 W91-10793

OCCURRENCE OF APPENDIX IX ORGANIC CONSTITUENTS IN DISPOSAL SITE CONSTITUENTS IN DISPO GROUND WATER, Lockheed-EMSCO, Las Vegas, NV.

Ground Water Monitoring Review GWMRDU, Vol. 11, No. 2, p 157-164, Spring 1991. 1 fig, 2 tab, 9 ref. U. S. Environmental Protection Agency Contract Nos. 68-03-3050 and 68-03-3245.

Descriptors: \*Groundwater pollution, \*Hazardous wastes, "Monitoring, "Organic pollutants, "Pollutant identification, "Waste disposal, Cost analysis, Data interpretation, Databases, Pesticides, Sampling, Volatile organic compounds.

Monitoring data from 479 disposal site investiga-Monitoring data from 4/2 disposal site in conditions were used to provide an initial estimate of the occurrence and distribution of 208 Appendix IX organic constituents in groundwater. The most occurrence and distribution of 208 Appendix IX organic constituents in groundwater. The most prevalent class of contaminants were the volatile organic compounds, which accounted for 84 percent of all the detectable events in the composite data set involving Appendix IX organic constituents. The abundance of the remaining subsets of Appendix IX organic constituents decreased in the following order: base/neutral compounds (8.6 percent), acid extractable compounds (3.5 percent), pesticides (3.0 percent), Resource Conservation and Recovery Act (RCRA) pesticides (0.6 percent), and non-priority pollutants (0.25 percent). The current regulatory requirement to monitor for Appendix IX organic constituents is approximately Appendix IX organic constituents is approximately Appendix IX organic constituents is approximately four times more expensive than monitoring for conventional priority pollutants (volatile, base/neutral, acid extractable, and pesticide compounds). Because the non-priority pollutant compounds account for an estimated 76 percent of the Appendix IX analytical costs but only 0.25 percent of the detectable events in disposal site groundwater, it has been recommended that this class of compounds be deleted from reuting monitoring compounds be deleted from routine monitoring programs. A scaling back of the current require ment to the conventional priority pollutants would still target more than 99 percent of the Appendix IX organic constituent occurrences in groundwat-er and would result in substantial analytical cost savings. Descriptors: \*Data interpretation, \*Model studies, Peats in the second of the sec

It has been recognized that macropores allow a analysis of the second second

arrival of the solute at any given depth occurring at much less than one pore volume displaced. A detailed mechanistic model of water movement and transport of non-reactive solute in a macroporous soil was developed which considers water and ous soil was developed which considers water and solute transport in a soil profile divided into layers, which may be of varying thickness, with an upper boundary at the soil surface and a lower boundary at a specified depth. In the two-dimensional version of the model, the total soil porosity in each layer is divided into interacting flow regions (i.e., page 2002-2014). macropores and micropores), each of which is characterized into a water content and a flux. In preliminary model applications, a sensitivity analysis was performed for water discharges and solute breakthrough curves under steady rain inputs. A comparison made between the output from the one-domain and the two-domain models illustrated the conditions under which a second flow domain may need to be considered. The simulations suggested that decisions concerning the need to con-sider a second flow domain certainly depend on the scale of the soil structure, and are influenced by initial and boundary conditions. BIOCHEMICAL AND HISTOCHEMICAL OB-SERVATIONS ON EFFECTS OF LOW-LEVEL METAL LOAD (LEAD, CADMIUM) IN DIF FERENT ORGAN SYSTEMS OF THE FRESH-WATER CRAYFISH, ASTACUS ASTACUS L, (CRUSTACEA: DECAPODA),

raerztliche Hochschule Hannover (Germany, F.R.). Inst. fuer Zoologie. W. Meyer, M. Kretschmer, A. Hoffmann, and G.

Harisch. Ecotoxicology and Environmental Safety EESADV, Vol. 21, No. 2, p 137-156, April 1991. 8 fig, 85 ref.

Descriptors: \*Bioaccumulation, \*Crayfish, \*Heavy metals, \*Path of pollutants, \*Toxicity, \*Toxicology, \*Water pollution effects, Cadmium, Crustaceans, Enzymes, Hazard assessment, Invertebrates, Lead, Tissue analysis.

The biological impact of heavy metals in aquatic systems has become a major concern in recent years. One of the most interesting aspects, in particular in view of long-term effects, is the influence of low-level heavy metal concentrations on different ecological systems. The effects of low-level lead (20 micrograms/L) exposure on the structure and function of different organ systems of Astacus astacus were estimated by several biochemical and histochemical methods. The animals were incubatnistocnemical methods. The animals were incubated during 10 weeks (max.) at a temperature of 10 C and a normal diurnal rhythm. Lead accumulated in high amounts exercically in the discounting the second like in the second lin and a normal diurnal rhythm. Lead accumulated in high amounts especially in the digestive gland, carapace, and gills, whereas the hindgut and musculature exhibited very low lead levels. Cadmium accumulated particularly in the digestive gland and gills. Lead and cadmium levels were definitely lower in the digestive gland, gills, and carapace of animals incubated in water containing a double, i.e., lead and cadmium load, than in animals kept in water containing only one of these heavy metals. Histochemically, both metals could be visualized in a typical distribution within the tissues, such as the carapace, digestive gland, or gills. After several weeks of poisoning, all organs, especially the digestive gland, showed severe structural damage. The activities of oxidative enzymes in the digestive gland and gills were significantly lowered after 2 weeks of incubation. Enzyme histochemical evaluation demonstrated changes of reaction intensities uation demonstrated changes of reaction intensities within the organs as compared to the controls.

GSH S-transferase activities and GSH contents were also distinctly decreased following lead and/or cadmium intoxication. The histochemical demonstration of SH and S-S groups exhibited a stronger staining reaction after 10 weeks of expo-sure, especially in digestive gland and gills. (Au-thor's abstract)

STUDIES ON THE ENVIRONMENTAL PER-SISTENCE OF S-31183 (PYRIPROXYFEN): AD-SORPTION ONTO ORGANIC MATTER AND POTENTIAL FOR LEACHING THROUGH

California Univ., Parlier. Mosquito Control Research Lab.

C. H. Schaefer, E. F. Dupras, and F. S. Mulligar Ecotoxicology and Environmental Safety EESADV, Vol. 21, No. 2, p 207-214, April 1991. 1 fig, 3 tab, 11 ref. USDA Cooperative Agreement No. 82-CRSR-2-1010.

Descriptors: \*Leaching, \*Nonpoint pollution sources, \*Path of pollutants, \*Pesticides, \*Soil analysis, \*Soil contamination, \*Wastewater lagoons, Analytical methods, Mosquitoes, Organic matter, Pyriproxyfen, Soil columns, Soil types

Analytical methods were developed to allow the extraction and analysis of S-31183 (pyriproxyfen), 2-(1-methyl-2-(4-phenoxypethoxy) pyridine, in organic matter from animal wastewater lagoons. Analysis of water and organic debris from lagoons. Analysis of water and organic deons from a treated lagoon showed that the active ingredient readily adsorbed into organic matter. S-31183 per-sisted on organic matter for over a 2-month period, during which time the concentration decayed at an exponential rate. In leaching trials with four different soil types, over 50% of the active ingredient applied remained in the upper 6 cm of a 30 cm soil column; there was no indication of a rapid potential for downward migration. The use of S-31183 that for downward migration. The use of 8-31185 for treating wastewater lagoons at doses which are effective for mosquito control did not result in any apparent problems of environmental incompatibility. Aliphatic hydrocarbons present in the tissues of samples of Sardina pilchardus, a plankton-ivorous fish, from the Adriatic Sea were analyzed to determine the presence, origin (biogenic or fossil) and metabolic fate of the hydrocarbons which reach metabolic face of the hydrocarbons which reach the fish from the environment. Samples were ob-tained from off the coast of Emilia-Romagna (Italy) during the months of December, April, June and September. The highest amounts of total hydrocarbons were detected in June and Septemer, the lowest in April, and intermediate levels in December. Among tissues, the highest concentra-tions were found in mesenteric fat. Predominant hydrocarbons were n-C-17 (saturated) and isoprenoid squalene (unsaturated). The uniformity of the qualitative distribution of these compounds in the qualitative distribution of these compounds in the various tissues analyzed showed that these hydrocarbons undergo limited metabolic change. Based on the presence of n-C-17 olefins with 17 and 19 carbon atoms and heneicosahexaene, it is assumed that these hydrocarbons isolated from the tissues of

#### Sources Of Pollution-Group 5B

S. pichardus are of recent biological and not of fossil origin. However, it must be emphasized that this fish is pelagic and is able to leave a heavily polluted zone. The composition of the isolated hydrocarbons excludes the possibility in the samples analyzed of petroleum contamination by human activities along the Adriatic coastline. (Medina-PTT) W91-10839

Surface sediments were collected in the Gulf of Lions and in the Rhone delta (France) and analyzed for composition of polycyclic aromatic hydrocarbons (PAH). After isolation of lipids, the drocaroons (FAM). After isolation of pipus, the hydrocarbons were separated into fractions by high-performance liquid chromatography (HPLC) and fractions were analyzed by gas chromatography (GC) and gas chromatography/mass spectrometry (GC/MS). Annual PAH fluxes were calculated for the northwestern Mediterranean basin. The fluxes of open-sea sediments varied from 164 micrograms/sq m/yr for a station located far from the coast and influenced by atmospheric deposition, up to 1420 micrograms/sq m/yr for stations directly influenced by the Rhone river input, whereas stations located in the Rhone delta were whereas stations located in the Rhone delta were characterized by higher fluxes, up to 12,250 micrograms/sq m/yr. PAH concentrations decreased significantly with distance from the river mouth. Detailed analysis of PAH revealed the presence of anthropogenic compounds, pyrolytic and petrogenic, and naturally derived compounds. The distance of the presence of the pre genic, and naturally derived compounds in the tribution and ratios of specific compounds of PAH are analyzed as a function of morphological and sedimentological features to evaluate and characterize the respective importance of atmospheric terize the respective importance of atmospheric and Rhone-derived river inputs. Pyrolytic inputs from anthropogenic combustion processes were predominant at all stations. Compounds of natural origin were quantified, such as retene and related abietic acid precursors, and pentacyclic triterpenes derived from alpha and beta amyrins. Anthropogenic PAH fluxes, determined for an open-sea sediment corresponding to the end of the ninetaenth. genic PAH Illuxes, determined for an open-sea sedi-ment corresponding to the end of the nineteenth century (approximately 100 years ago), were three to four times less than the current flux; however, the retene flux was equal to or higher than that of today. Variations in partitioning as a consequence of the nutrient conditions was analyzed to use this infor-mation in mathematical models to predict the dis-persal rate of bacteria in aquifers. Two different models were used to describe dispersal: an advec-

tive-disvective-sorptive model with a first order kinetic sink term to account for irreversible cell reactions, such as death and sorption; and a twosite reaction model, in which the retardation was assumed to be determined by two types of sites, one characterized by instantaneous equilibrium sorption reactions and the other by kinetic nonequilibrium reactions. Water-saturated sand columns were used as continuous-flow groundwater microcosms to test the models under different nu-trient regimes. Two strains of indigenous groundwater bacteria were isolated from aquifer material. Both experimental data and model variables showed that dispersal of bacteria was a dynamic showed that dispersal of bacteria was a dynamic nonequilibrium process, possibly shaped by two subpopulations, one strongly, even irreversibly, adsorbing to the solid particles, and one with very slow adsorption kinetics. Cell surface hydrophobicity was about 8 times higher in groundwater than in eutrophic lake water. The partition coefficient varied between 12.6 in the groundwater and 6.4 in the lake water, indicating the prime importance of hydrophobic binding for attachment in low nutrient conditions. The partitioning was also sensitive to the hydrodynamics of the system and the oxygen supply, as demonstrated in a continuous flow cell. About 45% of the population was associated with sand particles with continuous flow of pure groundwater and as little as 20% in lake water. However, more than 50% of the bacteria in the aqueous phase were associated with suspended the aqueous phase were associated with suspended material of less than 60 micrometers in diameter. This association may enhance dispersal by size exclusion of the colloidal material in the interstitial spaces. (Medina-PTT) W91-10843

Results of research on the ecology of the Rhine and its tributaries undertaken between 1970 and 1990 were reviewed and compared with relevant data in the literature on the ecology of canalized rivers within the Rhine system and other large rivers in western Europe. The exchange processes between the Rhine river and the alluvial aquifer were analyzed in the upper part of the Rift Valley (upstream of Strasbourg). Hydraulic works, and the consequent suppression of flooding, along the Alsace Rhine floodplain greatly modified these processes. The transfer of persistent toxic micropollutants (organochlorine compounds, mercury), and non-persistent pollutants (organophosphorus compounds: Sandoz spill) from the Rhine to the groundwater-fed streams was shown by pollutant data in the literature on the ecology of canalized groundwater-fed streams was shown by pollutant bioaccumulation in fish (particularly eel) and eubioaccumulation in fish (particularly eel) and eutrophication of these streams near the canalized river. Comparison of the hydrological functioning of the two main river floodplains (the Rhine and its tributary, the III, in the Alsace Rhine plain) showed two completely different exchange processes: in the canalized Rhine, the groundwater is affected by direct transfer of pollutants through the channel bed. In the river III, where the floodplain is extensively flooded each year, the soil-root system of the alluvial forest and meadow very effectively purify the floodwaters transferred to the groundwater. OFF-RIVER STORAGES AS SOURCES AND SINKS FOR ENVIRONMENTAL CONTAMI-

Ok Tedi Mining Ltd., Port Moresby (Papua New

Guinea).

R. J. Higgins.

Regulated Rivers Research & Management RRRMEP, Vol. 5, No. 5, p 401-412, November/ December 1990. 6 fig, 5 tab, 18 ref.

Descriptors: \*Model studies, \*Off-river storage, \*Papua New Guinea, \*Path of pollutants, \*Water storage, Flood control, Flow discharge, Mine wastes, Sediment transport, Streamflow, Water

An off-river storage is one for which filling, storage, and draining behavior is governed by a water-course which does not pass through the storage area. Off-river storages accept water from their adjacent stream, often when streamflow is high, and may return water, to the stream when stream. and may return water to the stream when stream flow is low. In addition, they usually have a water catchment of their own, independent of the main stream, which may contribute a significant propor-tion of inflow to the storage in total or on some occasion. Off-river storages have many uses in-cluding water supply and flood mitigation, and can also be a significant resource in their own right. In also be a significant resource in their own fight. In the same manner that off-river storages receive, hold, and subsequently discharge water flow, so contaminants contained in the water column may be received, held, and released. However, the be received, need, and released. However, the timescale of contaminant retention and release may be quite different from that applying to water flows. Also physical, chemical and biological proc-esses in the storage may alter the nature of the contaminants, such that released materials have different environmental implications from those input. A conceptual model of the dynamics of these processes in an off-river storage has allowed identification of factors which must be considered in assessing each case, and provides a possible common approach to the analysis of different cases. The model was used to assess the possible cases. The model was used to assess the possible influence on off-stream storages of sediments in transport and the metal contained in these sediments which enter the Fly River of Papua New Guinea as a result of mining operations. Samples of muscle tissue from red morwong Cheilodactylus fuscus (Pisces: Cheilodactylidae) collodactylus fuscus (Pisces: Chellodactyludae) col-lected at 24 sites along the coast near Sydney, Australia, were analyzed for total concentrations of Hg, As, Se, Zn, Cd, Pb, Ni and Cu. The sites were equally spaced around each of the three major ocean disposal sewage treatment plants (STP) in Sydney located at North Head, Bondi and Malabar. The mean concentrations of Hg, As, and Maasoar. The mean concentrations of fig. 85, and Zn were highest in fish caught off Sydney Harbor and Malabar STP. The proportion of fish in which Cd was detected was also highest off Sydney Harbor and south of Malabar STP. Aver-Sygney runroor and south of maladar 31°. Average Se concentrations decreased from north to south with peak concentrations at each STP. Many individual values of Cu, Pb, and Ni were near or below the detection limits and no notable trends were observed for these metals. Hg was the only metal whose overall mean concentration exceeded the National Health and Medical Research Council Maximum Residue Limit. (Author's abstract) W91-10873

COEFFICIENT OF POLLUTION (P): THE SOUTHERN CALIFORNIA SHELF AND SOME

OCEAN OUTFALLS. California State Univ., Long Beach. Dept. of Biol-

D. Maurer, G. Robertson, and I. Haydock. Marine Pollution Bulletin MPNBAZ, Vol. 22, No. 3, p 141-148, March 1991. 8 fig, 1 tab, 7 ref.

Descriptors: \*California, \*Coefficient of pollution, \*Marine pollution, \*Path of pollutants, \*Pollution index, \*Wastewater outfall, \*Water pollution effects, Coastal waters.

The coefficient of pollution (p) was developed to measure the extent of contamination in coastal waters of the Mediterranean. This measure incorporates abiotic variables (granulometry and depth) that strongly influence fundamental biotic parameters (species composition, number of species, number of individuals) in a single index. Implicit in p is that excessive amounts of organic and inorganic waste modify the benthic fauna. These modifications may alter species composition, the order of abundance of species, reduce the number of species. abundance of species, reduce the number of species, and sometimes the number of individuals. cies, and sometimes the number of individuals. This coefficient was applied to the southern California shelf including three major ocean outfalls (Whites Point, Orange County, San Diego City). Values of p from the shelf were considerably lower than those reported for portions of the Gulf of Saronikos for which the coefficient was originally developed. Corrections to an earlier application of p to Whites Point did not change major conclusions, but did change the magnitude of values, reducing them in this case. Within the California shelf there were regional differences in p at various outfalls. There was a significant reduction of p at Whites Point between 1973-84. Values of p at the Orange County outfall were generally

lower than at the other outfalls. The development of an integrated (abiotic-biotic) measure of pollution incorporating granulometry and depth and basic community parameters (number of species and number of individuals) is highly desirable. (Author's abstract) W91-10874

TAR BALLS ON IBENO-OKPOSO BEACH OF SOUTH-EAST NIGERIA.
Calabar Univ. (Nigeria). Inst. of Oceanography.

F. E. Asuquo.

Marine Pollution Bulletin MPNBAZ, Vol. 22, No.

3, p 150-151, March 1991. 2 fig, 1 tab, 5 ref.

Descriptors: \*Beach contamination, \*Marine pollu-tion, \*Nigeria, \*Offshore platforms, \*Oil pollution, \*Oil spills, \*Path of pollutants, \*Tar balls, \*Water pollution, Seasonal variation, Wave action.

A study was undertaken to quantitatively assess the standing stock of tar and to investigate the prevalent oceanographic factors influencing the level of tar on the Ibeno-Okposo beach of southlevel of tar on the Ibeno-Okposo beach of southeast Nigeria. The highest monthly amount of tar collected during a survey of 30 stations along a 25 km beach front in 1988 was 1.39 g/sq m/m in January; the lowest was 0.04 g/sq m/m in October. Generally, high levels of tar were recorded between January and May (>0.30 g/sq m/m). Except in May, a low amount of tar was recorded during the rainy season (June-October, <0.2 g/sq m/m). Tar balls ranged from <10 mm to 8.5 cm in diameter. The amount of tar obtained during the diameter. The amount of tar obtained during the period was relatively low, with the maximum value 63% and 25% of the maximum values in 1985 and 1986, respectively. This reduction is attained to the period was relatively low. and 1960, respectively. This reduction is at-tributed to the absence of reported major oil spill incidents, suggesting that only relatively small amounts of oil entered the marine environment from minor spills. With the presence of large offshore oil platforms adjoining the beach studied, high levels of tar balls would have been expected to be deposited due to the combined effects of spilled oil from offshore production and other sources. The low tar content reported in this study is partly attributed to the short beach front caused by the existence of transient beach scarps and by the existence of transpirate beach scarps and partly to the influence of dominating spilling breaker waves associated with flat beach profiles. The scarps impede the transportation of tar to the supralittoral, thereby impeding the amount of tar left by waves after each swash action. (Sand-PTT) W91-10876

BIOACCUMULATION, ELIMINATION AND METABOLISM OF TRIPHENYLTIN CHLO-RIDE BY EARLY LIFE STAGES OF MINNOWS

PHOXINUS PHOXINUS, Eidgenoessische Anstalt fuer Wasserversorgung, Abwasserreinigung und Gewaesserschultz, Due-bendorf (Switzerland).

bendorf (Switzerianu). K. Fent, R. Lovas, and J. Hunn. Naturwissenschaften NATWAY, Vol. 78, No. 3, p 125-127, March 1991. 2 fig, 1 tab, 9 ref.

The accumulation, depuration, and metabolism of triphenyltin (TPT) chloride in embryos and/or yolk fry of the minnow Phoxinus phoxinus were investigated. In the first series of experiments, ferinvestigated. In the first series of experiments, fertilized eggs were exposed for 192 h to determine the uptake during both embryonic and larval stages. In the second set of experiments, freshly hatched larvae were exposed for 144 h to determine uptake, and for 192 h to determine uptake

and subsequent elimination. TPT and its metabolites diphenyltin and monophenyltin were analyzed by capillary gas chromatography with flame photometric detection. The experiments showed a rapid uptake of TPT from water, while an elimination was absent during the 96-h observation period. There was a linear relationship between the external concentration of TPT and body weight. Whole-body tissue concentrations of TPT did not reach between which indicates that the bioaccuse. reach plateaus, which indicates that the bioaccu-mulation is even higher in larvae than determined in these experiments. Thus, the calculated biocon-centration factors for TPT (concentration in wet centration factors for 1P1 (concentration in wet tissue/initial concentration in water) being 530 in the embryonic/larval exposure after 192 h, and 457 and 930 after 96 h and 144 h, respectively, in the larval exposure, underestimate the real bioconcen-tration factors. The TPT elimination from larval tration factors. The LFT elimination from farvitissue was extremely slow, and the metabolites remained very low in tissue during uptake and elimination, suggesting an absence or a very slow catabolism of TPT. This behavior of TPT--the high potential for bioaccumulation, rapid uptake, and low elimination and metabolism--is similar to other organic compounds that have a known high bioaccumulation potential. The behavior, transport and ultimate fate of con-taminants in subsurface environments may be af-fected significantly by their participation in sorp-tion reactions and related phenomena. The degree to which the resulting effects can be quantified and predicted depends upon the extent to which cer-tain fundamental aspects of sorption are under-stood, and upon the accuracy with which these phenomena can be characterized and modeled in complex subsurface systems. This review covers current levels of understanding of the reactions current levels of understanding of the reactions and processes comprising sorption phenomena, and the forms and utilities of different models used to describe them. Emphasis is placed on concept development, on the translation of these concepts and models into functional models for characterizing sorption rates and equilibria, and on the application of these concepts and models for explaining contaminant behavior in subsurface systems. Examples are provided to illustrate the impacts of sorption phenomena on contaminant transport. (Author's abstract) W91-10882

HYDROCARBONS IN URBAN RUNOFF: THEIR CONTRIBUTION TO THE WASTEWATERS.

carbons, \*Storm wastewater, \*Urban runoff, Aliphatic hydrocarbons, Automobile exhaust, Carcinogens, Petroleum products, Seasonal variation,

A hydrocarbon characterization analysis was applied to extractable organic matter from Madrid runoff. The effects of traffic densities as well as seasonal and meteorological influences were considered. The main contribution is the exhausts from vehicles, which are distinguished by the presence of petroleum residues in the form of aliphatic and aromatic hydrocarbons. Polycyclic aromatic hydrocarbons. drocarbons with carcinogenic potency ever also identified from incomplete combustion products in automobile exhausts. Natural hydrocarbons derived from higher vascular plants are present on residential and landscaped areas in high levels. W91-10885

VOLATILE ORGANIC COMPOUNDS IN TWO POLLUTED RIVERS IN BARCELONA (CATA-LONIA, SPAIN).

Centro de Investigacion y Desarrollo, Barcelona (Spain). Dept. of Environmental Chemistry. J. I. Gomez-Belinchon, J. O. Grimalt, and J.

Albaiges. Water Research WATRAG, Vol. 25, No. 5, p 577-589, May 1991. 5 fig, 4 tab, 20 ref. Spanish National Plan for Research Grant NAT89-0927.

Descriptors: \*Barcelona, \*Coastal waters, \*Marine pollution, \*Path of pollutants, \*Spain, \*Stream pollution, \*Volatile organic compounds, \*Water pollution sources, Benzense, Besos River, Chlorinated hydrocarbons, Llobregat River, Naphthalenes.

The distributions of volatile organic compounds The distributions of volatile organic compounds (VOC) in two rivers flowing through heavily populated areas, Besos and Llobregat, were investigated. River waters were analyzed monthly for 13 months. Marine samples from the coastal area where the rivers discharge as well as from other coastal sites situated away from river influence were also studied. Petrogenic hydrocarbons, essentially C1-C5 alkylbenzenes and C8-C20 n-alkanes, are the major VOC present in these rivers (estimated annual discharge 260 metric tons). Chlorinated benzenes, C10-C13 alkylbenzenes, some terpenes and tributylohosphates are other main VOC with oenzenes, Clo-Cl3 aikyloenzenes, some terpenes and tributylphosphates are other main VOC with estimated outputs to seawater of 22, 14, 7 and 2 metric tons per year, respectively. The VOC concentrations in the rivers are generally between 2-3 centrations in the rivers are generally between 2-3 orders of magnitude higher than in the marine samples. The discharges of the Besos and Llobregat Rivers result in significant increases of C10-C13 alkylbenzenes, tributylphosphate, hexachlorobutadiene and chlorobenzenes to the nearby coastal area. However, in the case of petrogenic hydroards and area. carbons, the background concentration resulting from marine traffic and related activities developed in the area outnumbers the riverine contributio (Author's abstract) W91-10887

FATE OF ACETONE IN AN OUTDOOR MODEL STREAM WITH A NITRATE SUPPLEMENT, SOUTHERN MISSISSIPPI, U.S.A.

MENT, SOUTHERN MISSISSIFT, U.S.A. Geological Survey, Arvada, CO. R. E. Rathbun, D. W. Stephens, and D. Y. Tai. Journal of Hydrology JHYDA7, Vol. 123, No. 3/4, p 225-242, March 1991. 2 fig, 10 tab, 13 ref.

Descriptors: \*Acetone, \*Biodegradation, \*Fate of pollutants, \*Nitrates, \*Streams, Degradation, Nutrients. Traveltime.

The fate of acetone in an outdoor model stream to which nitrate was added as a nutrient supplement was determined. The stream, in southern Mississippi, was 234 m long. Water was supplied to the stream by an artesian well at about 1.2 L/s, result-

ing in a mean water velocity of about 20-40 mg/L ing in a mean water velocity of about 20-40 mg/L.

A nitrate solution was injected continuously for 26
days resulting in concentrations of about 1.7 mg/L
at the upstream end of the stream. Rhodamine-WT
dye was used to determine the travel time and
dispersion characteristics of the stream, and t-butyl
alcohol was used to determine the volatilization
characteristics. Volatilization controlled the fate of acetone in the model stream. The lack of substan tial bacterial degradation of acetone was contrary to expectations based on the results of laboratory degradation studies using model stream water enriched with nitrate. A possible explanation for the lack of significant degradation in the model stream may be the limited 6-h residence time of the accetone in the stream. (Author's abstract) W91-10903

chemistry, Soil properties, Streams, Water table.

Concerns over the effects of acid rain have stimu lated numerous hydrometric and geochemical studies on forested watersheds with an emphasis on stream water chemistry. However, integrated stud-ies are seriously lacking, and inferences on soil hydrogeochemical processes from periodic stream water chemistry may be grossly misleading. A small forested subcatchment was intensively instrumented for hydrologic and chemical analyses to improve the understanding of the processes that control subsurface transport of solutes. The timing and volume of subsurface flows were found to be highly dependent upon soil hydromorphologic properties. Development of perched water tables was the predominant mechanism of subsurface through the lower layers during moderate to flow through the lower layers during moderate to high flow events. Perching of water was insignificant during low flow events and only partially responsible for lateral flow through the upper soil layers during moderate events. The importance of non-equilibrium conditions during even low flow events was illustrated by the occurrence of saturated flow through unsaturated (matric potentials < 2 Pa) soil. The initial subsurface flow response of a moderate and high flow event was predominantly (>70%) new water that bypassed the soil matrix. As flows continued the percentage of old water increased. Intermittent rainfall during the high flow event caused multiple peaks in subsurface flow with subtle increases in perching. This sugflow with subtle increases in perching. This sug-gests an increase in the portion of infiltrating water gests an increase in the portion of the macropores that bypasses soil matrix water via macropores causing increases in subsurface flow with limited growth of perched water tables. The persistence of perched water tables as flow decreased was con-sistently observed. Decreases in solute concentrations causes decreases in conductivity of pores was inferred as one mechanism for this. (See also W91-10908) (Author's abstract)

HYDROGEOCHEMICAL PROCESSES CON-TROLLING SUBSURFACE TRANSPORT FROM AN UPPER SUBCATCHMENT OF WALKER BRANCH WATERSHED DURING STORM EVENTS. 2. SOLUTE TRANSPORT PROCESSES

Descriptors: \*Acid rain effects, \*Geochemistry, Descriptors: "Acid rain effects, "Geochemistry, "Groundwater movement, "Path of pollutants, \*Solute transport, "Storm seepage, "Subsurface water, \*Watersheds, Hydrographs, Infiltration, Kinetics, Mass balance, Nutrients, Porosity, Slopes, Soil chemistry, Soil water, Suspended solids.

Geochemical studies of transport from watersheds have focused on stream chemistry and/or soil lynave locused on stream chemistry and/or soil lysimeter data to interpret soil processes. Direct measurements of subsurface transport of solutes from hillslopes during storm events and integration with hydrometric analyses is seriously lacking. The subsurface transport of solutes (K, Ca, Mg, Mn, Fe, Al, Na, SO4, and Si) from a 0.47 ha hillslope subcatchment of the west fork of Walker Branch watershed for six storm events is presented. Transport of Fe and Al was primarily as suspended particles which resulted in a very rapid increase in their concentrations at the initiation of subsurface flow. Weathering via particle detachment (i.e., sus-pended particles) was believed to be due to rapid pended particles) was beneven to be use of infiltration of new water of low ionic strength which increases the diffuse double layer facilitating detachment of particles. The concentration of Fe and Al in filtered solutions increased as flow and decreased during the recession limb of the hydrograph. The mechanisms for the increase then decrease is believed to be electrostatic exchange from surfaces of conducting pores followed by a kineti-cally controlled release via mineral decomposition. most commonly observed solute transport pattern during storm events was an increase in contern during storm events was an increase in centration as flow rate increased, followed by a decrease in concentration during the recession limb of the hydrograph. This response was due to flush-ing of solutes primarily from water-filled mesopores with macropores serving as conduits for solutes with limited attenuation. A mass balance of solutes was computed for the subcatchment for 1988, and subsurface storm flow through the upper soil profile resulted in only a minor export of deposited solutes. However, subsurface saturated flow during individual storms were shown to be significant exporters of nutrients. (See also W91-10907) (Author's abstract) W91-10908

NITRATE REMOVAL BY DENITRIFICATION IN ALLUVIAL GROUND WATER: ROLE OF A FORMER CHANNEL.

Centre National de la Recherche Scientifique, Toulouse (France). Centre d'Ecologie des Res-sources Renouvelables.

2,4-Dichlorophenol, in trace amounts, has been identified as a metabolite of the herbicide 2,4-dichlorophenoxyacetic acid (2,4-D) in laboratory soils although its isolation and identification in 2,4-D treated field soils remains to be demonstrated. The transformation of (C-14)-2,4-dichlorophenol in The transformation of (C-14)-2,4-dichlorophenol in four soils was investigated by measuring amounts of (C-14) carbon dioxide evolved, quantifying solvent-extractable C-14 products, and determining the incorporation of radioactivity into soil organic matter. Over a 14-day period in four soils with no recent herbicide history, 12-17% of the applied C-14 was released as carbon dioxide, 5-23% of the initial radioactivity was solvent recoverable as (C-14)-2,4-dichloroanisole. Unknown volatile C-14 products and unidentified solvent-extractable C-14 compounds together accounted for 3-6% of the applied C-14. Between 44 and 68% of the initial radioactivity was associated with soil organic matter. The c-1+. Detween 44 and 68% of the initial radioactivity was associated with soil organic matter. The present studies indicate that should any 2,4-dichlorophenol come into contact with the soil as a result of 2,4-D metabolism, such residues would be rapidly dissipated. (Agostine-PTT) W91-10922

REMOBILIZATION OF CU FROM MARINE PARTICULATE ORGANIC MATTER AND FROM SEWAGE.

Oceanic and Atmospheric Administration Pacific Marine Environmental Laboratory Contribution

Descriptors: \*Copper, \*Heavy metals, \*Marine pollution, \*Organic matter, \*Particulate matter, \*Path of pollutants, \*Wastewater, Decomposition, Diffusion, Effluents, Flocculation, Ion exchange, Puget Sound, Sediments

The possible causes of enrichments of dissolved Cu in the bottom waters of Puget Sound were examined in a series of experiments designed to measure the release of Cu from surface marine organic suspended matter and from sewage-derived particles under ambient conditions. Decomposition of organic matter and ion-exchange controlled the release of about one-third of the Cu bound to large particles ( > 53 micrometer). In contrast, no Cu was released from smaller particles ( < 53 micrometers) suspended in natural seawater and only 5% of the Cu on small particles was released into artificial seawater with a low dissolved Cu concentrations. or the Cu on small particles was released into artificial seawater with a low dissolved Cu concentration. Within 15 min of mixing primary effluent with natural seawater, 40% of the dissolved Cu was lost from solution by flocculation. Between 15 min and 4 days, 25% of the total effluent Cu was released back into solution. This release could have critical efficiency of the control originated either from particulate Cu on the original sewage particles or from the flocculated Cu that was formed from dissolved Cu within the first that was formed from dissolved Cu within the first 15 min. The release of Cu into the bottom waters of Puget Sound from settling marine organic matter was calculated to between 1 and 8 microgram Cu/sq-m day, which is comparable with the diffusion of Cu from sediments. In contrast, the

release of sewage-derived Cu could have been as high as 725 microgram Cu/sq-m day within 10 km of outfall. (Author's abstract) W91-10923

DISTRIBUTION OF DISSOLVED CADMIUM, LEAD AND COPPER IN THE BRISTOL CHAN-NEL AND THE OUTER SEVERN ESTUARY. Ministry of Agriculture, Fisheries and Food, Burn-ham on Crouch (England). Fisheries Lab. D. I Harper.

nam on Stoute Carlon Records of the Control of the Chemistry MRCHBD, Vol. 33, No. 1/2, p 131-143, April 1991. 5 fig, 18 ref.

Descriptors: \*Cadmium, \*Copper, \*Estuarine environment, \*Heavy metals, \*Lead, \*Path of pollutants, \*Water pollution sources, Bristol Channel, Chemical properties, Distribution patterns, Industrial wastes, Salinity, Severn Estuary.

A reassessment of trace metal distributions around the English and Welsh coastlines has been under-taken by the Ministry of Agriculture, Fisheries and Food's laboratory at Burnham-on-Crouch. As part of this series of surveys, one cruise included an on this series of surveys, one cruise included an investigation of trace metal levels in the Bristol Channel and outer Severn Estuary. The sampling covered an area from Avonmouth in the east to a north-south transect at 5 degrees west. Seawaters in regions that were known to receive a significant anthropogenic input, such as Swansea Bay and the Severn estuary, were sampled more intensively than in regions with little or no input from industry. In October 1987 63 samples were taken from 50 stations in the Bristol and outer Severn estuary 30 stations in the Bristol and outer Severn estuary on the west coast of England. The distributions of dissolved cadmium, lead and copper are reported together with their relationships to salinity. The concentration ranges are 11-140 ng/L for cadmium, 20-10000 ng/L for lead and 1.7-4.7 microgram/L for copper. In high-salinity areas, higher cadmium and copper concentrations users found to cadmium and copper concentrations were found to be associated with local inputs, but the situation with respect to lead was found to be more compli-cated. At lower salinities, lead and copper distribu-tions show several anomalies as a result of processtions show several anomanes as a least of processes other than dilution. The data obtained at low salinities may not be typical, because the survey was carried out after a period of unusually high winds and rainfall. (Agostine-PTT) W91-10925

NON-POINT SOURCE LOADINGS OF NUTRI-ENTS AND DISSOLVED ORGANIC CARBON FROM AN AGRICULTURAL-SUBURBAN WA-TERSHED IN EAST CENTRAL FLORIDA. Florida Inst. of Tech., Melbourne. Dept. of Chemi-cal and Environmental Engineering.

F. E. Dierberg. Water Research WATRAG, Vol. 25, No. 4, p 363-374, April 1991. 8 fig, 5 tab, 23 ref.

Descriptors: \*Agricultural watersheds, \*Florida, \*Nonpoint pollution sources, \*Organic loading, \*Suburban areas, \*Urban runoff, \*Water pollution sources, Canals, Dissolved organic carbon, Drainage, Nutrient transport, Storms, Watersheds.

Unit area loadings for nitrogen, phosphorus dissolved organic carbon were measured from four sub-watersheds and the entire 256 sq-km catchment area tributary to the Indian River Lagoon. The catchment area is a rapidly growing suburban area drained by 322 km of canals in east central Florida. One-third of the annual total nitrogen, one-half of the total phosphorus and one-fourth of the annual dissolved organic carbon were exported in the drainage canal water at the water control structure to downstream waters during a 6-week period when three major storms occurred. High annual loadings of dissolved inorganic (1.3 kg N/ha-yr) and organic (4.4 kg N/ha-yr) nitrogen were recorded for the rotational grazing sub-watershed; during storm search the entire discolved increasing during storm events, the entire dissolved inorganic nitrogen load leaving the catchment basin originated from the agricultural sub-watershed. Annual total nitrogen and total phosphorus export coefficients from the agricultural sub-basin deviated considerably from published 'national' averages, but were very similar to 'regional' coefficients pub-lished for Wisconsin. Dissolved inorganic nitrogen and phosphorus had wide variances to the published 'regional' coefficients, emphasizing the need for site-specific studies. (Author's abstract) W91-10927

INCIDENCE OF LEGIONELLA IN URBAN ENVIRONMENT IN AUSTRALIA.

University of Technology-Sydney, Broadway.
Div. of Biological Sciences.
L. J. Hedges, and D. J. Roser. Water Research WATRAG, Vol. 25, No. 4, p 393-399, April 1991. 5 tab, 26 ref.

Descriptors: \*Australia, \*Domestic water, \*Epidemiology, \*Legionella, \*Path of pollutants, \*Urban areas, Climates, Geography, Air conditioning, Pathogens, Pollutant identification, Water quality

Extensive sampling of the built environment was undertaken to determine the extent of Legionella presence in different regions of New South Wales. Distribution and abundance of Legionella in N.S.W. were found to be similar to those found in Europe and North America, despite Australia's present all inserts and generating indiction. warmer climate and geographical isolation. Air conditioning cooling towers, warm water systems and spas showed the highest incidence of Legion-ella (32, 37 and 36% respectively). Legionella ophila serotypes predominated, being in 82% of the positive samples examine pneumophila being Seasonality in isolation patterns was not detected.
The Illawarra Health Region, where a major out-break has recently occurred, was found to have the lowest incidence of Legionella, probably due to improved maintenance measures undertaken in the aftermath of the outbreak. It was concluded that the distribution and abundance of Legionella in the the distribution and abundance of Legionelia in the south-eastern part of Australia follows a comparable pattern to elsewhere in the world and that measures to prevent outbreaks of Legionnaire's disease should be similar to those currently being introduced in the U.S.A. and Great Britain. (Author's abstract)

RIPARIAN ZONE AS A SOURCE OF PHOS-PHORUS FOR A GROUNDWATER-DOMINAT-ED LAKE.

DYNAMIC MODEL OF CAESIUM TRANS-PORT IN LAKES AND THEIR CATCHMENTS. Institute of Hydrology, Wallingford (England). S. McDougall, J. Hiltlon, and A. Jenkins. Water Research WATRAG, Vol. 25, No. 4, p 437-445, April 1991. 6 fig, 1 tab, 18 ref.

Descriptors: \*Cesium, \*Cesium radioisotopes, \*Fallout, \*Lakes, \*Model studies, \*Path of pollut-ants, \*Watersheds, Air pollution effects, Chernobyl accident, Epiliminon, Fish, Hypolimnion, Runoff, Sedimentation, Suspended solids.

A mathematical model has been developed to predict radiocesium concentrations over time within individual compartments of a lake and its catch-ment. The lake is divided into five compartments; (1) catchment, lake water ((2) epilimnion and (3) hypolimnion during stratification), (4) lake sediment and fish. Radiocesium enters the lake via contaminated rainfall and catchment runoff. A proportion of the radiocesium absorbs onto suspended solids in the lake. This proportion is represented by a distribution coefficient. Sedimentation of the suspended solids occurs at a rate defined by the areal removal coefficient and results in increased cesium removal coefficient and results in increased cesium concentrations in the sediment. The ingestion of radiocesium by either water column or benthic feeding fish is described by transfer functions. The model has been tested against data collected from Esthwaite water and Windermerer shortly after the Chernobyl reactor accident from May 1986 to December 1987. The model simulates observed radiocesium concentrations in Esthwaite lake water and sediment and also in lake water, sediment and fish in Windermerer. The model could ment and fish in Windermere. The model could

form the basis of a valuable management tool for the water industry should a major airborne pollu-tion ever occur again. (Author's abstract)

SEASONAL CHANGES IN THE SANITARY BACTERIAL QUALITY OF WATER DRAIN-ING A SMALL UPLAND CATCHMENT IN THE YORKSHIRE DALES.

Leeds Polytechnic (England). School of the Envi-

C. Hunter, and A. McDonald. Water Research WATRAG, Vol. 25, No. 4, p 447-453, April 1991. 3 fig, 4 tab, 20 ref.

Descriptors: \*Animal wastes, \*Bacteria, \*Drainage area, \*England, \*Nonpoint pollution sources, \*Path of pollutants, \*Watersheds, Cattle, Coliforms, Overland flow, Rainfall, Sheep, Soil contamination, Water quality management, Water quality monitoring.

The fecal coliform concentration of overland flow The fecal coliform concentration of overland flow and streamwater within a small catchment in the Yorkshire Dales was monitored over a 2 year period. Strong and consistent seasonal trends in bacterial concentrations were found. During the height of summer (mid June to the end of August), fecal coliform concentrations in streamwater were found to be significantly higher than at other times of the year. Consistently low concentrations were found during winter months. These trends closely followed those identified for semi-permanent overland flow, suggesting a direct causal link between streamwater quality and the bacterial concentraand now, suggesting a direct causar into detween streamwater quality and the bacterial concentra-tion of overland flow entering the stream channel. The seasonal trends identified were explained with respect to long term changes in the size of the store respect to long term changes in the size of the store of enteric bacteria existing in the surface soils of the catchment. Changes in land store size were related to seasonal changes in the frequency and amount of rainfall input to the catchment. The implications of the research findings for the management of upland catchments used for water supply or recreation are discussed. The most obvious potential solution to this problem would be to reduce substantially the influence of semi-permanent overland flow. This could be achieved by (1) lowering the water table close to stream channels through the installation of drainage systems or (2) through the installation of drainage systems or (2) to exclude sheep or cattle access (through fencing) from those catchment areas most frequently involved in the generation of overland flow. (Author's abstract) W91-10935

BIOAVAILABILITY OF ORGANIC POLLUT-ANTS IN BOREAL WATERS WITH VARYING LEVELS OF DISSOLVED ORGANIC MATERI-

AL. Joensuu Univ. (Finland). Dept. of Biology. J. Kukkonen, and A. Oikari. Water Research WATRAG, Vol. 25, No. 4, p 455-463, April 1991. 8 fig, 4 tab, 38 ref. Academy of Finland/Research Council for Environmental Sciences project no. 06/133.

Descriptors: \*Bioavailability, \*Cold regions, \*Dis-solved solids, \*Hydrophobic compounds, \*Organic pollutants, \*Path of pollutants, Benzopyrene, Fin-land, Physical properties, Polycyclic aromatic compounds, Surface water, Waterfleas.

Dissolved organic matter (DOM) in 20 surface waters in Eastern Finland were characterized to examine relationships between structural and compositional properties of DOM and partition coefficients (Kp) describing sorption of four model contaminants to DOM and the bioavailability of contaminants by Daphnia magna. The hydrophobic acids (HbA), hydrophobic neutrals (HbN) and hydrophiolic (HI) fractions were separated by XAD-8 resin. The Kps were measured by equilibrium dialysis. Model contaminants were benzo(a)pyrene (BaP), naphthalene (NAPH), 3,3',4,4'-tetrachlorobiphenyl (TCB) and dehydroabietic acid (DHAA). DOM concentrations varied from 2.0 to 38.3 mg org. C/L in the water series. The percentage of HbA and the aromaticity of DOM, as indicated by the absorptivity at 270 nm (A-270) and hydrogen/carbon ratio, increased with increasing DOM con-

centration. Significant correlations were observed between Kp of BAP, A-270 and HbA content of the DOM form different sources. For the other contaminants similar kinds of relationships between Kps and quality parameters of DOM could not be found. The bioavailability of model compounds was decreased by increasing DOM concentration in the water series. For all four model contaminants, measured bioconcentration factors correlated well with the A-270 of a water and HbA content of the DOM. These results show that the total DOM concentration is an important factor controlling the bioavailability of xenobiotics in natural waters. In addition to the quantity, the quality of DOM, like proportion of HbA, can contribute to bioavailability. (Author's abstract)

EVIDENCE OF CHERNOBYL FALLOUT ON A TEMPERATE HIMALAYAN GLACIER. Physical Research Lab., Ahmedabad (India). V. N. Nijampurkar, and D. K. Rao. Current Science CUSCAM, Vol. 59, No. 23, p 1239-1241, 1990. 1 fig, 9 ref.

Descriptors: \*Air pollution, \*Chernobyl, \*Fallout, \*Glaciers, \*Himalayas, \*India, \*Nuclear accidents, Air pollution effects, Alps, Path of pollutants, Radioactive wastes, Snow sampling, Soviet Union.

Several snow/ice samples collected in August 1987 from Chhota Shigri glacier, in the Indian Himalayas, were analyzed for total beta and gamma activities to see if any fallout from the Chernobyl, anyas, were analyzed for total beta and gamma activities to see if any fallout from the Chernobyl, nuclear accident in April 1986 was deposited in the Himalayan region. It was found that the activities in snow samples were higher, by a factor of about 15, than those observed in old ice samples. These activities were mainly in the hump region of the glacier located in the altitude band 4150 to 4650 m. The total activities are much lower, as expected, than those observed in the Alps, which indicates that a very small fraction of the Chernobyl fallout was deposited over the Himalayas as compared to that in the Alps. These results are the first evidence of Chernobyl fallout deposition on Chhota Shigri glacier. The radioactivity must have eventually been diluted with large volumes of air in the atmospheric reservoir before deposition in the Himalayan region. (Fish-PTT)

PROSPECTING FOR ZONES OF CONTAMINATED GROUND-WATER DISCHARGE TO STREAMS USING BOTTOM-SEDIMENT GAS BUBBLES.

Geological Survey, Columbia, SC. Water Resources Div.

D. A. Vroblesky, and M. M. Lorah. Ground Water GRWAAP, Vol. 29, No. 3, p 333-340, May/June 1991. 6 fig, 23 ref.

Descriptors: \*Bubbles, \*Groundwater pollution, \*Maryland, \*Path of pollutants, \*Volatile organic compounds, \*Water pollution sources, Analytical methods, Bottom sediments, Chloroform, Decom-posing organic matter, Fluvial sediments, Gases, Trichloroethylene.

Because the installation of observation wells at sites of groundwater contamination is expensive and proper placement of wells is necessary to ensure that suspected contaminant plumes are intercepted, reconnaissance methods that can intercepted, reconnaissance methods that can detect and delineate possible areas of groundwater contamination are important to the design of a cost-efficient and functional monitoring network. Decomposition of organic-rich bottom sediment in a tidal creek in Maryland results in production of gas bubbles in the bottom sediment during summer and fall. In areas where volatile organic contaminants discharge from groundwater, through the

bottom sediment, and into the creek, part of the volatile contamination diffuses into the gas bubbles and is released to the atmosphere by ebullition. Collection and analysis of gas bubbles for their volatile organic contaminant content indicate that volatile organic contaminant content indicate that relative concentrations of the volatile organic contaminants in the gas bubbles are substantially higher in areas where the same contaminants occur in the groundwater that discharges to the streams. Analyses of the bubbles located an area of previ-Analyses of the bubbles located an area of previously unknown groundwater contamination. The method developed consisted of disturbing the bottom sediment to release gas bubbles, and then capturing the bubbles in a polyethylene bag at the water-column surface. The captured gas was transferred either into sealable polyethylene bags for immediate analysis with a photoionization detector or by syringe to glass tubes containing wires coated with an activated-carbon adsorbent. Relative consentations were determined by some seasons. tive concentrations were determined by mass spec-tral analysis for chloroform and trichloroethylene. (Author's abstract) W91-10951

CHARACTERISTICS OF RHODAMINE WT AND FLUORESCEIN AS ADSORBING GROUND-WATER TRACERS.

Oklahoma Univ., Norman. School of Civil Engi-Okianoma Univ., Norman, School of Civil Engineering and Environmental Science.
D. A. Sabatini, and T. A. Austin.
Ground Water GRWAAP, Vol. 29, No. 3, p 341-349, May June 1991. 8 fig, 6 tab, 23 ref.

Descriptors: \*Chemical tracers, \*Dye releases, \*Dyes, \*Path of pollutants, \*Pesticides, \*Solute transport, \*Tracers, Adsorption, Alachlor, Atrazine, Groundwater movement, Herbicides, Sand

Fluorescent dyes are being used as adsorbing groundwater tracers for conducting solute transport studies for adsorbing organic chemicals (e.g., pesticides). The ability of two fluorescent dyes (rhodamine WT and fluorescein) to mimic the adventise and the adventise of the behinder (strains and the adventise of the behinder of the period of the period of the adventise of the behinder of the period of the adventise of the period of the (rhodamine WT and fluorescein) to mimic the ad-sorptive behavior of two herbicides (atrazine and alachlor) with alluvial aquifer sands was evaluated. Laboratory studies (batch and column) indicated the following order of increasing adsorption: fluo-rescein, atrazine, alachlor, and rhodamine WT. Thus, the use of fluorescein and rhodamine WT as adsorbing groundwater tracers was observed to delimit the appearance of the atrazine and alachlor (fluorescein; anneared before and rhodamine WT. delimit the appearance of the atrazine and alachlor (fluorescein appeared before and rhodamine WT after the herbicides). Several adsorption characteristics of the fluorescent dyes differed from those commonly observed for pesticides. The levels of adsorption for the dyes were several orders of magnitude greater than predicted from empirical relationships based on the octanol-water partition coefficient and the function of the organic carbon content of the material. The presence of divalent cations was observed to increase the level of rhodamine WT adsorption. The rhodamine WT break-through curves were not of the conventional significant of the several conventional significant carbon contents. through curves were not of the conventional sig-moidal shape but instead leveled off at a carbon to moidal shape but instead leveled off at a carbon to carbon monoxide ratio (C/CO) value of 0.5 for a number of pore volumes prior to increasing again towards a C/CO value of 1.0. These characteristics indicate that the adsorptive mechanisms for the fluorescent dyes differed from the adsorptive mechanisms for most pesticides. These variations in fundamental adsorptive mechanisms raise concerns as to the transferability of the results of this research (fluorescein and rhodamine WT delimiting the appearance of atrazine and alachlor) to other subsurface media. #### Group 5B-Sources Of Pollution

\*Path of pollutants, \*Solute transport, \*Subsurface mapping, Electrical equipment, Water table gradi-ent, Water table profiles.

Vertical electrical soundings were used to map the vertual recent a soundings were used to map the presence or absence of an aquitard separating a shallow, contaminated aquifer from a deeper, uncontaminated one in San Bernardino Valley, California. Correlation of vertical electrical soundings with lithologic logs from adjacent wells allowed mapping of local variations in the elevation of the water table. Comparison of known waste sites, the distribution of the aquitard, and elevation of the water table yielded probable directions of contaminant transport. It was concluded that there is a significant hazard to municipal water wells due to possible transport of contaminants between the shallow and deeper aquifers. (Author's abstract) W91-10960

POLYCHLORINATED BIPHENYLS IN DATED SEDIMENT CORES FROM GREEN BAY AND

LAKE MICHIGAN.
Wisconsin Univ.-Milwaukee. Dept. of Civil Engi-

M. H. Hermanson, E. R. Christensen, D. J. Buser, and L. M. Chen.

Journal of Great Lakes Research JGLRDE, Vol. 17, No. 1, p 94-108, 1991. 8 fig. 3 tab, 51 ref. U.S. Environmental Protection Agency assistance agreement R810419; U.S. National Science Foundation Grant No. CES-8701184.

Descriptors: \*Core analysis, \*Green Bay, \*Lake Michigan, \*Lake sediments, \*Polychlorinated biphenyls, \*Water pollution sources, Air pollution, Dating, Great Lakes, Radioactive dating, Sedi-

Widespread use of polychlorinated biphenyls (PCB) in industrial and consumer products for nearly 50 years between 1929 and 1977 has resulted in the presence of this class of compounds in every environmental compartment. Ten sediment cores from Lake Michigan and Green Bay were ana-lyzed for PCB, 210-Pb, and 137-Cs. Analyses in-cluded identification of historical patterns of PCB inputs to the lake and bay and estimation of histori-cal annual average PCB fluxes to the sediment that cal annual average PCB fluxes to the seatment that were corrected for sediment redistribution (focus correction). A correction for focusing has not been utilized in previous investigations of PCB flux to Lake Michigan and Green Bay sediments. From these analyses, it was concluded that PCB inputs have declined following the 1977 ban on new used of PCB, and that the strosphere is the largest of PCB, and that the atmosphere is the largest source of PCB to parts of Lake Michigan. It is estimated that the average annual atmospheric flux to the Lake Michigan region is about 1.0 ng/sq cm/yr, plus-or-minus 0.34, which is the approxi-mate flux to three of five Lake Michigan cores. This amount is consistent with another recent flux This amount is consistent with another recent flux estimate. Green Bay sediments have higher PCB concentrations and greater relative amounts of lower molecular weight PCB (Aroclor 1242) than lake sediments which are dominated by Aroclor 1254. Aroclor 1260 is also found in Green Bay but not observed in the lake. PCB concentrations in Green Bay sediment are highest near the mouth of the Fox River, and decline in areas of the bay where the Fox River plume is more dispersed. Atmospheric inputs account for no more than 11% of PCB flux to any Green Bay core analyzed. (Author's abstract) (Author's abstract) W91-10979

PHOSPHORUS FROM INTERNAL SOURCES IN THE LAURENTIAN GREAT LAKES, AND THE CONCEPT OF THRESHOLD EXTERNAL LOAD.

Freshwater Research, R.R. 1, Baysville, Ontario P0B 1A0.

G. K. Nurnberg. Journal of Great Lakes Research JGLRDE, Vol. 17, No. 1, p 132-140, 1991. 2 fig, 4 tab, 32 ref.

Descriptors: \*Great Lakes, \*Lake sediments, \*Limnology, \*Phosphorus, \*Pollution load, \*Limnology, \*Phosphorus, \*Pollution load, \*Water pollution sources, Anoxic conditions, Eutrophication, Hypolimnion, Nutrient transport, Sediments, Trophic level.

The trophic status of the Laurentian Great Lakes is greatly influenced by phosphorus (P) derived from anoxic sediment surfaces. Data from the Great Lakes and data from smaller lakes of Eastern North America can be used to demonstrate how such an internal P load influences trophic state. To facilitate predictions for the future of the Great Lakes or any lake subjected to P release from anoxic sediment surfaces, the concept of 'threshold external load' is introduced. The external P load at which the flux downward from external sources matches the flux upward from anoxic sediments can be considered the 'threshold external load.' The product of the 'threshold external load.' the Ine product of the 'threshold external load,' the gross P retention (predicted from the annual water load) and the ratio of lake surface area to hypolimnetic area (a sediment focusing factor) yields the anoxic P release. The concept of 'threshold external load' helps explain the slow response of certain lakes to phosphorus input abatement. (Author's obstract)

LEACHING OF AMMONIUM NITRATE UNDER FIELD CONDITIONS: STUDIES ON KINETICS OF NITRIFICATION AND NITRATE REDUCTION IN AN ULTISOL PRO-

Orissa Univ. of Agriculture and Technology, Bhubaneswar (India).

B. K. Mishra, and C. Misra. Journal of Hydrology JHYDA7, Vol. 124, No. 1/ 2, p 185-195, April 1991. 4 fig, 3 tab, 13 ref.

Descriptors: \*Ammonium, \*Leachates, \*Leaching, \*Nitrates, \*Nitrification, \*Path of pollutants, \*Solute transport, India, Nutrient transport, Sandy soils, Soil chemistry, Soil columns, Soil properties

Owing to microbial activity, NH4(+)-N present in, or added to, the aerobic surface soil layer is oxidized to NO3(-)-N, which, while moving through the underlying aerobic soil layers, may be denitrified to an extent depending upon the interplay of a number of factors influencing the behavior of microbes in the soil environment. The interplay of a number of factors influencing the behavior of microbes in the soil environment. The interplay of a number of factors influencing the behavior of microbes in the soil environment. ior of microbes in the soil environment. The simultaneous occurrence of nitrification and nitrate re-duction was studied by leaching solution pulses of MHANO3 through 9 cm long columns and natural field profile of Bhubaneswar, India, sandy loam soil (Ultisol). Employing known analytical solutions of transport equations relevant to conditions induced for the leaching experiments, the nitrate reduction rate constant was estimated to be 0.072/. h at 28 C based on the breakthrough curve (BTC) of NO3(-)-N stemming from the soil column through which Ca(NO3)2 was leached. Using this value of the nitrate reduction constant, the value of nitrification rate constant was estimated to be 0.06/ h by curve fitting the NO3(-)-N BTC derived from NH4NO3 leaching in an equivalent soil column. Using values of the nitrate reduction constant close to that derived from the laboratory column studies, the nitrification rate constant was evaluated to be 0.1/h and 0.04/h for 0-30 and 0-50 cm soil layers, respectively, under field situations. OIL SPILL RISK SIMULATION MODEL. Kuwait Inst. for Scientific Research, Safat. Envi-ronmental and Earth Sciences Div.

Journal of Waterway, Port, Coastal and Ocean Engineering (ASCE) JWPED5, Vol. 117, No. 3, p 285-300, May/June 1991. 8 fig, 2 tab, 22 ref.

Descriptors: \*Computerized maps, \*Model studies, \*Oil slicks, \*Oil spills, \*Path of pollutants, \*Risk assessment, \*Simulation analysis, Coastal waters, Coastal zone management, Mapping, Markov process, Probabilistic process, Spills, Time series analysis, Wind-driven currents.

Oil spills are a major environmental concern in coastal regions. Most oil-slick models consider the coalsair regions in the collision of collisions movement a primarily deterministic mechanism, useful for hindcasting spill movement. When it comes to the problem of forecasting, however, oil-slick movement should be statistically simulated. A simulation numerical model has been simulated. A simulation fundered indoor has been developed that can generate an oil-risk map for a given area. The map shows monthly and yearly probabilities of oil-slick presence for each grid area. The probability computation procedure includes the oil-slick movement at each time stage cludes the oil-sinck movement at each time stage until it completes the given time interval. An ex-ample was examined to generate the Kuwait oil-spill risk map by using the simulation model. The results of the oil-spill risk map can be used to determine the relative sensitivities of coastal sec-tions where oil-slick occurrence are most probable. nons where outsince occurrence are most probable. The decision maker can use this information for strategic planning in environmental protection and for selecting sites for seawater intakes, fish farms, and coastal recreation areas. The model simulates a spill's location, size, and associated movement based on statistical data. Horizontal wind vector components are simulated using a Markovian time series model based on local wind statistics. The simulation of the slick's movement includes the mechanisms of spreading and drift by wind and currents. (Author's abstract) W91-11001

POLITICAL ECONOMIC MODEL OF INTER-NATIONAL POLLUTION

Minnesota Univ., St. Paul. Dept. of Agricultural and Applied Economics.

H. Von Witzke, and M. L. Livingston.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 119-128, 4 fig,

Descriptors: \*Economic aspects, \*Great Lakes, \*International waters, \*Model studies, \*Path of pollutants, \*Political aspects, \*Water pollution sources, \*Water quality, Costs, Industrial wastes, International agreements. Interstate commissions.

International pollution (externalities that cross po-International poliution (externations that cross po-litical jurisdictions) represents one of the most economically and politically complex problems. Calls for institutional changes that reduce interna-tional pollution grow with economic development and the accumulation of environmental degradation. Single countries, however, can supply them-selves with such institutions only in cooperation with other countries. Therefore, any solution to the problem requires explicit recognition of both political and economic aspects involved. Under-standing the political and economic determinants standing the pointed and economic determinants of existing water quality regulations is an important precondition for the development of feasible policy strategies that can lead to improved water quality in the Great Lakes. A public choice model is presented that captures the incentive structures faced by resource users, and the marginal political and economic benefits and costs of regulation. The precific conditions which give rice to calificial to the conditions which give rice to conditions which give and economic benefits and costs of regulation. The specific conditions which give rise to political cooperation or conflict are also specified. Hypotheses concerning the optimal degree of regulation as viewed by individual jurisdictions are posited with regard to: (1) the relative political strength of producers and consumers; (2) the transaction costs faced by each group; (3) structure of the input market; (4) relative size of the polluting industries involved; (5) level of economic development; and (6) the amount of the externality is properted; to or (6) the amount of the externality 'exported' to or 'imported' from other states or provinces. This analysis suggests a number of reasons for the exist-

### Sources Of Pollution—Group 5B

ence of policies that allow the private sector to deviate from the social optimum if there are exter-nalities in production. If part of the domestically produced externality is 'exported' to third countries, total domestic output of the externality is higher than in the case in which the total domestic higher than in the case in which the total domestically production of the externality is consumed domestically. The existence of an externality from abroad leads to a lower domestic output of the externality and a higher total consumption of the externality. This represents an incentive for policy coordination. The existing incentives for policy cooperation, however, do not imply that international coperation actually will occur. For this to happen, issues of fairness of the distribution of benefits of such agreements among countries will have to be such agreements among countries will have to be fully addressed. HEAVY METAL TRANSPORT TO THE GREAT LAKES BY NATURAL GROUND-WATER DISCHARGE: AN INITIAL EVALUATION.

Syracuse Univ., NY. Dept. of Geology.
D. I. Siegel, S. Frape, A. Martini, R. Drimmie, and

R. Thomas. IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 605-613, 2 fig,

Descriptors: \*Geochemistry, \*Great \*Groundwater discharge, \*Heavy metals, \*Path of pollutants, \*Water pollution sources, Brines, Canada, Detroit River, Dissolved solids, Geohydrology, Groundwater movement, Groundwater pollution, Groundwater quality, Lake Erie, Lake Huron, Lake Michigan, Lake Ontario, Niagara River, United States

The introduction of heavy and other trace metals to the Great Lakes is a significant environmental problem affecting the United States and Canada. Past studies have focused on the transport of heavy Problem antecting the Office States and Canada. Past studies have focused on the transport of heavy metals to the lakes from rivers such as the Niagara and Detroit. These rivers receive contaminated groundwater mostly from shallow flow systems. However, groundwater flow systems in the bedrock formations located along the margins of Lakes Erie, Ontario, Michigan and Huron also discharge heavy metals to the lakes. This groundwater naturally has a high concentration of dissolved solids, up to hundreds of thousands of parts per million, and concentrations of heavy metals hundreds to thousands of times greater than those found in most contaminated rivers. It can be shown from a synthesis of data from regional groundwater flow models, geohydrologic field studies, and studies of brine chemistry, that heavy metal transport to the Great lakes by natural groundwater discharge may be equal to or even greater than heavy metal transport from contaminated rivers. Dakshina Kanada district which lies between the Arabian Sea and the Western Ghats (Sahyadri Mountain Chain) in southern India, remained un-derdeveloped until very recently, notwithstanding its rich natural resources. Of late, intense developmental activities have begun in the coastal region. mental activities nave begun in the coastal region. These have been putting a great strain on the fresh water potential of the district. Even though the district receives heavy annual rainfall, it faces water scarcity problems from early summer (March to May). An assessment of harnessible water potential has, therefore, become imperative. A case study was conducted in an attempt to assess the long-term average monthly computer progri Results indicate that the basin has a harnessi Results indicate that the basin has a harnessible potential of water, and that the untapped ground-water can be availed from the basin area, when the monsoon breaks, without disturbing agricultural activity. By making use of the surplus water, about 5,671 ha of unirrigated land can be brought under irrigation. Water quality studies indicate the presence of good quality water except in lower reaches where some of the wells are polluted due to salt water intrusion. The regression models developed for water quality are found to be highly useful in water intrusion. The regression modes developed for water quality are found to be highly useful in the prediction of water quality when it is not possible to analyze a large number of samples for all physicochemical characteristics of water. ENVIRONMENTAL PROBLEMS AND SOLU-TIONS: GREENHOUSE EFFECT, ACID RAIN,

POLLUTION.
Hemisphere Publishing Corporation, New York.
1990. 525p. Edited by T. Nejat Veziroglu.

Descriptors: \*Acid rain, \*Air pollution effects, \*Air pollution sources, \*Carbon dioxide, \*Global warming, \*Greenhouse effect, \*Oil spills, \*Path of pollutants, \*Radioactive wastes, \*Water pollution effects, \*Water pollution sources, Acidification, Air temperature, Climates, Clouds, Corrosion, Desertification, Drought, Estuaries, Flooding, Lakes, Rainfall, Rivers, Sea level.

Human activities have produced increasing amounts of destructive agents, including the green-house effect, acid rain, air pollution, radioactive pollutants, and oil spills. The large increase in carbon dioxide has initiated the greenhouse effect, which is thought to be responsible for the rise in air temperatures. The greenhouse effect is also causing climatic changes. Wind patterns are changing and as a result, the cloud movements and the locations where the rain falls are changing causing ere the rain falls are changing, causing

drought and floods in new locations. Higher tem peratures are causing the ocean levels to rise. Acid rains are causing acidification of lakes, rivers, and estuaries, with loss of aquatic life. They are also causing desertification, deforestation, and corrosion of structures. (See W91-11067 thru W91-11085) (Brunone-PTT) W91-11066

ATMOSPHERIC CARBON DIOXIDE AND THE GLOBAL CARBON CYCLE: THE KEY

Oak Ridge National Lab., TN. Environmental Sci-

T. H. Peng, W. M. Post, D. L. DeAngelis, V. H. Dale, and M. P. Farrell.

Date, and M. P. Partell.

17-38. 1 fig. 2 tab, 56 ref. US DOE Contract DEAC05-840R2140.

Descriptors: \*Air pollution, \*Atmospheric chemistry, \*Carbon cycle, \*Carbon dioxide, \*Mathematical models, \*Model studies, \*Path of pollutants, Anthropogenic effects, Biogeochemistry, Estimating, Marine environment, Organic carbon, Uncertainty.

The biogeochemical cycling of carbon determin the rate of increase in atmospheric carbon dioxide concentrations. The observed increase is less than the estimated release from fossil fuel consumption and deforestation. This discrepancy can be ex-plained by interactions between the atmosphere and other global carbon reservoirs such as the oceans, and the terrestrial biosphere, including soils. Results from studies of past fluctuations in atmospheric carbon dioxide and climate suggest that current carbon cycle models that emphasize human disturbances may overlook natural feedback components involving both terrestrial and marine systems. Because of current uncertainties in marine systems. Because of current uncertainties in atmospheric carbon dioxide fluctuations over the last 200 years, the contribution of non-fossil carbon sources cannot be satisfactorily explained. The physical, chemical and biological processes of carbon dioxide uptake can probably only come from mathematical models. Unfortunately, one-dimensional and two-dimensional ocean models do not allow for enough carbon dioxide uptake to accurately account for known releases. More complex three-dimensional models may make better use of existing tracer data than do one-dimensional and two-dimensional and will also incorporate cliand two-dimensional and will also incorporate cli-matic feedback effects to provide a more realistic view of ocean dynamics and carbon fluxes. In describing the various carbon dioxide exchanges between the atmosphere and terrestrial syster estimates of the net release of carbon to the atm phere from deforestation are incompatible with ocean model carbon dioxide uptake. Furthermore, the estimated loss rate of terrestrial organic carbon from biota and soils is so small compared to the total mass of organic carbon that these losses are largely undetectable and can only be estimated indirectly from models. Approaches must be adopted that emphasize both data and model improvements, keying in on critical uncertainties, and addressing areas where no easy solutions exist or where knowledge is needed. ### Group 5B-Sources Of Pollution

Present knowledge about future carbon concentraresent knowledge about ruture carroot concentrations in the atmosphere is extremely imprecise. Doubling appears most likely around the year 2070, but a significant probability (22%) exists, on the basis of current information, that doubling will occur before the year 2050. The three major sources of uncertainty that emerge are (1) the rate of productivity growth, (2) the elasticity of substitutions of the productivity growth, (2) the elasticity of substitutions are the productivity growth, (2) the elasticity of substitutions are the productivity growth, (2) the elasticity of substitutions are the productivity growth, (2) the elasticity of substitutions are the productivity growth. tution of energy sources, and (3) the bias in energy-based technological change towards nonfossil fuel Extrapolative models are essentially one-equation global models, with three key variables: total resources of carbon-based fuels, initial growth rate, and a qualitative judgement about the future pat-tern of resource exploitation. Results of models showed that (1) the doubling of carbon dioxide concentrations in the atmosphere is predicted to occur later than has been previously suggested; (2) productivity growth and future trends in technology affecting noncarbon-based fuels relative to gy affecting noncarbon-based fuels relative to carbon-based fuels are the most important areas of uncertainty affecting future carbon dioxide concentrations; and (3) population growth and world resources of carbon-based fuel account for 11% of the variance in emissions projected for the year 2100. ACID PRECIPITATION: A REVIEW.
Dow Chemical U.S.A., Midland, MI. Dept. of
Environmental Quality.

U. M. Cowgill. In: Environmental Problems and Solutions: Greenhouse Effect, Acid Rain, Pollution. Hemisphere Publishing Corporation, New York. 1990. p sphere Publishin 111-137, 160 ref.

Descriptors: \*Acid rain, \*Acid rain effects, \*Liter-ature review, \*Path of pollutants, \*Water pollution sources, Attitudes, Fuel, Hydrogen ion concentra-tion, Land use, Legislation, Nitric acid, Nitrogen, Precipitation, Sulfur, Sulfuric acid.

Acid precipitation philosophies are divided into two groups. Group I holds the view that this environmental problem requires legislative attention, that such precipitation results chiefly from the combustion of fossil fuels which release oxides of N and S into the atmosphere. Once present, N and S may undergo transformation to their respective acids and these substances may be transported great distances. Once deposited, these acids cause damage not only to all components of the natural landscape, but also to statues, monuments, builddamage not only to an components of the natural landscape, but also to statues, monuments, buildings and other anthropogenic materials. In addition, this group has the opinion that this phenomena has persisted since the mid-1950's; that the problem has worsened and the area affected is proneem has worsened and the area affected is steadily expanding. Proponents of Group I present data illustrating a mean decline of 0.5 pH units below the norm for rain (pH 5.6) in the regions affected. Group II offers several alternative expla-nations for the reported and sometimes observed phenomena. They suggest that acid conditions nations for the reported and sometimes observed phenomena. They suggest that acid conditions noted in water bodies result from drastic changes in land use, that reexamination of historical data reveal these data to be trendless, that local and natural sources of N and S oxides, especially resulting from the combustion of oil, play a major role in the feet of the state of the stat the formation of acidic precipitation in the region at risk. Finally, Group II attests that quantitatively attributing the phenomena of acid rain falling in one place to its origin in another place is difficult. Meteorological physiological, biological aspects of meteorological physiological, nological aspects of acid precipitation are reviewed from these two points of view, with emphasis on the known and the unknown in this complicated area of research. CHEMICAL COMPOSITION OF INDIVIDUAL STORMS AS A FUNCTION OF AIR PARCEL TRAJECTORIES FOR THE PREDICTION OF ACID RAIN CHARACTERISTICS.
British Columbia Ministry of Environment, Victo-

ria. Waste Management Branch. M. S. Kotturi.

In: Environmental Problems and Solutions: Greenhouse Effect, Acid Rain, Pollution. Hemi-sphere Publishing Corporation, New York. 1990. p 139-148. 3 fig. 7 tab, 5 ref.

Descriptors: \*Acid rain, \*Air pollution sources, \*Atmospheric chemistry, \*Chemistry of precipitation, \*Storms, British Columbia, Canada, Hydrogen fluoride, Hydrogen ion concentration, Path of pollutants, Rainfall, Sulfur dioxide.

The effects of local industrial emissions on pretation chemistry were tested in northwestern British Columbia. In the study area, in addition to general precursors to acid rain like sulfur dioxide (16 tons/day), the presence of hydrogen fluoride (2.18 tons fluoride/day) presents a unique situation in western Canada. To assess the impact of sulfur dioxide and hydrogen fluoride emissions on pH, event precipitation samples were collected and analyzed. The data showed that the fluoride concentration in ambient air decreased with increased precipitation. The acidity and fluoride concentra-tion in rain were higher in the summer than in other seasons, and the fluoride wet deposition rate was at a minimum in summer due to the heavy rainfall. Furthermore, the comparison of storm trajectories with observed ionic loading has offered an opportunity to qualitatively assess pollution re-ceived by rain water during storms from local individual industrial sources as well as distant natural and other sources. The presence of various pollutants has been monitored in drinking and groundwater in Jodhpur, tored in drinking and groundwater in Jodhpur, India. The waste water is slowly influencing the quality of the groundwater, which is a major source of the city's drinking water supply. Inorganic constituents, such as alkalinity, hardness, sulfate, phosphate, chloride, fluoride, dissolved oxygen, and iron have been estimated. Trace levels of cadmium, copper, lead and zinc have been measured using differential pulse polarography and differential pulse anodic stripping voltammetry. The

chemical oxygen demand has been used to measure chemical oxygen demand has been used to measure the degree of organic pollution strength in sewage and industrial waste water. The industrial waste water is highly toxic in nature, possessing a deep color (dark-red purple) accompanied by a foul smell. No aquatic life or vegetation is visible near the banks of the open drains in which the industrial effluent flows. The effluent has higher alkalinity, chloride and dissolved solid levels then permissible. The concentration of metal ions is within permissible limits, but phosphate is in excess. The untreated effluents of various industries pose a great risks to the environment of this area, by polluting the area in which they drain. (See also polluting the area in which they drain. ENERGY TRANSFORMATION-ECOLOGY INTERFACE FROM A NONLINEAR, NONE-QUILIBRIUM THERMODYNAMIC PERSPEC-

George Washington Univ., Washington, DC. Dept. of Civil, Mechanical, and Environmental Engineering. A. A. Oni.

In: Environmental Problems and Solutions: Greenhouse Effect, Acid Rain, Pollution. Hemi-sphere Publishing Corporation, New York. 1990. p 457-466. 17 ref.

Descriptors: \*Ecosystems, \*Energy transfer, \*Environmental effects, \*Equilibrium, \*Model studies, \*Path of pollutants, \*Thermodynamics, Fuel, Future planning, Powerplants, Prediction, Theoretical analysis, Water quality monitoring, Water resources management.

Non-linear, non-equilibrium thermodynamic methods are applicable to energy-ecology systems in general. Certain energy transformation-ecology interactions, involving the reactions of certain biotic variables to the various effects of power plant-generated air and aquatic pollution, are evaluated along a non-equilibration thermodynamic analogic path on the basis that the energy transformation-ecology interface constitutes a non-equilibrium anisotropic, open system in which irreversible tion-ecology interface constitutes a non-equilibrium, anisotropic, open system in which irreversible processes occur. A new formalism quantifies environmental quality on the basis of these irreversible processes, through the development of an explicit phenomenological scheme that relates those ecological phenomena to the energy transformation-ecology interface. A theoretical evaluation of the ecology interface. A theoretical evaluation of the quality of a typical ecosystem that includes a fossil fuel-electricity transforming power plant is conducted by means of the application of this formalism. A quality index, the Entropic Lump Index (ELD), is developed. The potential advantages of an exploratory approach include the ability to compare the quality of two environments and the comparative contributions to this quality by different types of plants. The approach would be perceived as supplementary to current environmental quality quantification methods. Also, opportunities exist for evaluating the cost-effectiveness of environmental quality improvement schemes by evaluating the incremental costs of each percentage ating the incremental costs of each percentage reduction in ELI. Finally, the index could indeed be utilized to prioritize allocation of monetary resources for environmental quality improvement. (See also W91-11066) (Brunone-PTT) W91-11085

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 90-4004, 1990. 131p, 14 fig, 9 tab, 86 ref, 5 append.

Descriptors: "Geophysics, "Groundwater pollution, "New Jersey, "Path of pollutants, "Waste disposal, "Water pollution sources, Aquifers, Benzene, Bicarbonates, Calcium, Conductivity, Displayed salids, Groundwater quality, Heavy metals, solved solids, Groundwater quality, Heavy metals, Iron, Manganese, Organic compounds, Regula-tions, Salinity, Sodium.

Five former or active industrial or waste disposal sites in Logan Township were identified by the Federal government and by the State of New Jersey as potential threats to the quality of groundwater there. The sites are: (1) Air Products and Chemicals, Inc. waste disposal site; (2) Bridgeport Rental and Oil Services, Inc.; (3) Chemical Leaman Tank Lines, Inc.; (4) Monsanto Company; and (5) Rollins Environmental Services, Inc. Shallow (<50 ft below land surface) ionic groundwater contamination at the waste disposal sites was delineated by electromagnetic conductivity. Quality of groundwater was determined by chemical ity of groundwater was determined by chemical analysis of samples from wells at four of the five sites and elsewhere in the township. Groundwater in the lower aquifer of the Potomac-Raritan-Magin the lower adjunter of the Potomac-Rantan-Mag-othy aquifer system in Logan Township and sur-rounding areas is dominated by sodium and chlo-ride ions and is slightly saline (1,000 to 3,000 mg/L dissolved solids). Calcium, sodium, and bicarbon-ate are the predominant ions in the upper and middle aquifers; the concentration of dissolved solids is low (< 1,000 mg/L). Concentrations of iron and manganese in the groundwater range from 6 to 73,000 microgm/L, and from 33 to 1,100 trom 6 to 73,000 microgm/L, and from 35 to 1,100 microgm/L. Concentrations of organic carbon range from 0.60 to 4.2 mg/L. Areas of high apparent conductivity (> 15 millisiemens/M) were detected east of the waste oil lagoon at the Bridgeport Rental and Oil Services, Inc. site. Inorganic groundwater contamination at the site is characterized by concentrations of cadmium and lead that exceed Federal and State primary drinking water regulations (10 and 15 microgm/L). Groundwater at the Chemical Learnan site also is characterized by elevated concentrations of organic nitrogen, and concentrations of As, Cr, Pb, and Hg that exceed Federal primary drinking water regula-tions. Concentrations of dissolved solids ranged from 339 to 3,530 mg/L at the Monsanto Site and typically are much higher than background levels, but the cause is unclear. (Lantz-PTT)

PRELIMINARY DATA SUMMARY FOR IN-DUSTRIAL LAUNDRIES. Available from the National Technical Information Service, Springfield, VA. 22161, as PB90-126541. Price codes: A09 in paper copy, A01 in microfiche. Report No. EPA 440/1-89/103, September 1989. 180p, 14 fig, 48 tab, 39 ref. EPA Contract Nos. 68-03-6302, 68-03-3545, and 68-03-3339.

Descriptors: \*Economic aspects, \*Environmental impact, \*Industrial wastewater, \*Laundering, \*Water pollution effects, \*Water pollution sources, Aquatic environment, Arsenic, Benzidine, Lead, Wastewater treatment, Zinc.

The US EPA has conducted a study of the industrial laundries industry in response to a recommendation made in the Domestic Sewage Study and because of concern for the potential discharge of toxic and hazardous pollutants. Industrial laundries (SIC 7218) are primarily engaged in supplying laundered or, to a limited extent, dry-cleaned work uniforms, wiping towels, safety equipment (gloves,

flame-resistant clothing), dust covers and cloths, and similar items to industrial or commercial users. Samples of raw wastewater, and treated final efflu-ent at laundries with wastewater treatment facilities, and waste solids were collected and analyzed for a wide variety of hazardous and nonhazardous pollutants. The results of the analyses showed that any of a large number of hazardous organic or metallic pollutants may be found in industrial laundry wastes at metallic pollutants may be found in industrial laundry wastes at concentrations that vary widely with location and time. Some hazardvary widely with location and time. Some hazard-ous pollutants were found at levels above 10 mg/ L. BOD5, total suspended solids, and oil and grease levels average approximately 1000 mg/L. Economic data characterizing the industrial laun-dries industry were compiled, and indicated that the number and size of industrial laundries and the number of employees and the revenues generated per facility were determined. The study showed per facility were determined. The study snowed that the industry comprises many rather small facilities and a few large ones which economically dominate the industry. There has been some growth in the industry in some regions of the country but overall there has been little growth country but overall there has been little growth. country but overall there has been little growth either in number of employees or revenue in the last twenty years. Three major influences on the industry are shown to be competition within an industry experiencing no significant growth, the availability of substitute goods and services, and availability of substitute goods and services, and environmental regulation. An environmental impact study evaluated the impacts of fourteen indirect discharging industrial laundries on public-ly owned treatment works (POTWs) and ultimately owned treatment works (POI Ws) and ultimate-ly on the POTW receiving streams. Two data sets were used for the environmental impact analysis, one from a 1986-1987 EPA industrial laundries wastewater effluent monitoring program and one from a similar 1978 EPA program. Only benzidine and arsenie exceed human health criteria and cya-nide exceeds chronic aquatic life criteria. Analysis of the 1978 data set projects water quality impacts. Six pollutants exceed human health criteria or chronic aquatic life criteria or both, and two pol-lutants (zinc and lead) exceed POTW inhibition levels. (Lantz-PTT) W91-11093

TECHNIQUES FOR ESTIMATION OF STORM-RUNOFF LOADS, VOLUMES, AND SELECTED CONSTITUENT CONCENTRATIONS IN URBAN WATERSHEDS IN THE UNITED STATES.

Geological Survey, Lakewood, CO. Water Re-

s Div.

N. E. Driver, and G. D. Tasker. Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Supply Paper 2363, 1990. 44p, 6 fig. 12 tab, 45 ref.

Descriptors: \*Model studies, \*Nonpoint pollution sources, \*Pollutant load, \*Statistical models, \*Storm runoff, \*Urban hydrology, \*Urban runoff, Ammonia, Data interpretation, Dissolved solids, Drainage, Land use, Nitrogen, Rainfall-runoff relationships, Regression analysis, Seasonal variation, Statistical methods, Urban areas.

Urban planners and managers need information on the quantity of precipitation and the quality and quantity of runoff in their cities and towns if they quantity of runoff in their cities and towns it they are to adequately plan for the effects of storm runoff from urban areas. As a result of this need, four sets of linear regression models were devel-oped for estimating storm runoff constituent loads, storm runoff volumes, storm runoff mean concen-trations of constituents, and mean seasonal or mean annual constituent loads from physical, land use, annual constituent loads from physical, and user, and climatic characteristics of urban watersheds in the United States. Thirty-four regression models of storm runoff constituent loads and storm runoff volumes were developed, and 31 models of storm runoff mean concentrations were developed. Ten models of mean seasonal or mean annual constitumodels of mean seasonal or mean annual constitu-ent loads were developed by analyzing long-term storm rainfall records using at-site linear regression models. Three statistically different regions, delin-eated on the basis of mean annual rainfall, were used to improve linear regression models where adequate data were available. Multiple regression analyses, including ordinary least squares and gen-

eralized least squares, were used to determine the optimum linear regression models. These models can be used to estimate storm runoff constituent loads, storm runoff volumes, storm runoff mean concentrations of constituents, and mean seasonal or mean annual constituent loads at gaged and ungaged urban watersheds. The most significant explanatory variables in all linear regression models were total storm rainfall and total contributing drainage area. Impervious area, land use, and mean annual climatic characteristics also were sigmean annual characteristics also were sig-inficant in some models. Models for estimating loads of dissolved solids, total nitrogen, and total ammonia plus organic nitrogen as nitrogen generally were the most accurate, whereas models for suspended solids were the least accurate. The most accurate models were those for application in the more arid Western States, and the least accurate models were those for areas that had large mean annual rainfall. CALIBRATION OF A TEXTURE-BASED MODEL OF A GROUND-WATER FLOW SYSTEM, WESTERN SAN JOAQUIN VALLEY, CALIFORNIA.

Geological Survey, Sacramento, CA. Water Reces Div.

S. P. Phillips, and K. Belitz.

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Open File Report 90-573, 1990. 30p, 13 fig, 2 tab. 30 ref.

Descriptors: \*California, \*Groundwater move-ment, \*Groundwater pollution, \*Model studies, \*Path of pollutants, \*San Joaquin Valley, \*Selenium, \*Soil texture, Hydraulic conductivity, Mathematical models, Sediment analysis, Soil water, Statistical analysis.

The occurrence of selenium in agricultural drain water from the western San Joaquin Valley, California, has focused concern on the semiconfined groundwater flow system, which is underlain by the Corcoran Clay member of the Tulare Formation. A two-step procedure is used to calibrate a reliminary model of the system for the purpose of determining the steady-state hydraulic properties are modeled as functions of the percentage of coarse sediment, hydraulic conductivities or coarse-texture (K-carse) and fine-textured (K-fine) end members, and averaging methods used to calculate equivalent hydraulic conductivities. The vertical conductivity of the Corcoran (K-corc) is calculate equivalent hydraulic conductivities. The vertical conductivity of the Corcoran (K-corc) is an additional parameter to be evaluated. In the first step of the calibration procedure, the model is run by systematically varying the following variables: (1) K-coarse/K-fine, (2) K-coarse/K-corc, and (3) choice of averaging methods in the horizontal and vertical directions. Root mean square error and bias values calculated from the model results are functions of these variables. These measures of interesting the amendation of the companion of the control of the contro functions of these variables. These measures of error provide a means for evaluating model sensitivity and for selecting values of K-coarse, K-fine, and K-core for use in the second step of the calibration procedure. In the second step, recharge rates are evaluated as functions of K-coarse, K-core, and a combination of averaging methods. The associated K-fine values are selected so that the root mean square error is minimized on the basis of the results from the first step. The results of the two-step procedure indicate that the spatial distribution of hydraulic conductivity that best produces the measured hydraulic head distribution is created through the use of arithmetic averaging in the horizontal direction and either geometric or is created through the use of antimetic averaging in the horizontal direction and either geometric or harmonic averaging in the vertical. The equivalent hydraulic conductivities resulting from either combination of averaging methods compare favorably to field-based and laboratory-based values. (Author's abstract)

Toxic waste sites contain from a few to a wide range of organic compounds. Many of these chemicals are at concentrations that may inhibit the biodegradation of others. Moreover, because of the frequent diversity of compounds present, their biodegradation probably involves the activities of several microbial species. In environments in which several synthetic organic chemicals are present, the biodegradation of one or more may be inhibited by the presence of others. In addition to the interspecific interaction in which one population, two or more species may interact if the inhibitory synthetics initially present, or those generated by microorganisms. are microbiologically dethe biodegradation of others. Moreover, because of by microorganisms, are microbiologically de-stroyed so that sensitive organisms may effect the biodegradation of substrates they otherwise might not be able to destroy. Therefore, a study was designed to determine the interactions that might occur when two chemicals (p-nitrophenol and 2,4 dichlorophenoxyacetate) at concentrations inhibitory to microorganisms are provided together to two bacteria (corynebacterium and pseudomonas) each of which can use one of the compounds. The factors determined to be of importance to these transformations and to proposed bioremediation actions were protozoan predation, inorganic nutrient supply, concentration of the test organic compound, the presence of inhibitors and alternative sources of biodegradable molecules, and the sorption and water solubility of the toxicants. TRANSPORT AND FATE OF ACETONE IN AN OUTDOOR MODEL STREAM, STENNIS SPACE CENTER NEAR BAY ST. LOUIS, MIS-

Geological Survey, Denver, CO. Water Resources

R. E. Rathbun, D. J. Shultz, D. W. Stephens, and

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 89-4141, 1989. 101p, 38 fig, 29 tab, 65 ref.

Descriptors: \*Acetone, \*Alcohols, \*Fate of pollutants, \*Model studies, \*Path of pollutants, Bacteria, Bay St Louis, Detritus, Flow velocity, Glucose, Mississippi, Nitrogen, Phosphorus, Volatilization.

Acetone, rhodamine-WT dye, t-butyl alcohol, and glucose were modeled in an outdoor stream to determine their fate and transportation in the system. Acetone was injected continuously for 32 days, resulting in concentrations in the 20 to 200 mg/L range in the stream water. Rhodamine-WT mg/L range in the stream water. Modamine-Wi dye was injected at the beginning and at the end of the experiment to determine the dispersion and traveltime characteristics of the stream. An injec-tion of t-butyl alcohol was used to determine the volatilization characteristics of the stream. A glu-cose solution was injected from day 17 through day 20 of the experiment in an attempt to stimulate the growth of bacteria in the stream water, with subsequent bacterial degradation of the acetone. Similarly, a nutrient solution containing bacteria acclimated to acetone in the laboratory was injected on days 23 and 24 in an attempt to stimulate the bacterial degradation of acetone. A diel oxygen study was conducted on days 11 and 12 of the

experiment to determine the productivity of the model stream. Conclusions resulting from this study are: (1) nitrogen/phosphorus ratios in the model stream were small relative to values from the literature considered desirable for efficient bacterial degradation of organic compounds; (2) the model stream was biologically rich and the bottom of the stream cross section contained a layer of organic detritus; (3) the mean residence time in the model stream, as determined from the dye studies was about 6 hrs; (4) mean water velocities and longitudinal dispersion coefficients determined in iongrudinal dispersion coefficients determined in the preliminary dye study and twice during the acetone-injection experiment generally were in good agreement. Mean velocities ranged from 0.317 m/min to 0.588 m/min and dispersion coeffi-cients from 0.300 sq m/min to 5.35 sq m/min for the different reaches of the stream; (5) volatilizathe different reaches of the stream; (3) Volanifiza-tion coefficients for acctone were in good agree-ment, with the exception of the day 4 values which, for the most part, were larger; (6) injection of a glucose solution resulted in no significant decrease in acctone concentrations in the model stream; (7) injection of the nutrient solution containing bacteria acclimated to acetone in the laboratory resulted in no apparent decrease in the acetone concentrations in the model stream. acetone concentrations (Lantz-PTT)

The organic xenobiotic compounds are of concern in sewage sludge therefore, the behavior and fluxes of linear alkylbenzenesulphonates (LAS), and non-ylphenolethoxylates (NPnEO) and the more toxic ylphenolethoxylates (NPnEO) and the more toxic NPnEO metabolites nonylphenol (NP), nonyl-phenolmonoethoxylate (NP1EO) and nonylphenoldiethoxylate (NP2EO) were investigated in sewage and sewage sludge treatment. Most of the particuand sewage sludge treatment. Most of the raw sewage late matter of the raw matter of the raw sewage and the excess activated sludge are removed in and the excess activated sludge are removed in the primary effluent of a wastewater treatment plant and will not be further subjected to aerobic treatment. Thus, the only aerobically degradable and lipophilic compounds, such as LAS and NP, become highly enriched in sewage sludge; in 1986 4 g LAS/kg total solids (TS) and 1.2 g NP/kg TS were found. In 1988, LAS has increased 40% (5.6 c/kg TS) and NP decreased 10%, (0.3 a kg/ 1.8 g total solids). g/kg TS) and NP decreased 70% (0.33 g/g TS) due to the NPnEO-ban in 1986. Therefore several hundred tons per year are spread on agricultural soil in Switzerland. Analysis of sludge amended soil showed that LAS and NP are still detectable several months after the last sludge application, suggesting that the behavior of these compounds, and compounds with similar chemical characteristics, should be thoroughly investigated in the soil ecosystem. Federal agencies are currently reviewing a planned study on the effects of agricultural practices on the occurrences of herbicides, insecticides, as well as other pesticides, and fertilizers in the mid-continen-tal United States. Atrazine was selected as the representative herbicide because of its history of extensive usage. The plan provides procedures that integrate information from a wide variety of integrate information from a wide variety of sources. A research matrix using a mass-balance concept was designed to account for the distribution of atrazine in a hydrologic system. Processes in the matrix include the major physical, chemical, and biological actions that may transform, transport, or store atrazine in the hydrologic system. This matrix will be applied at three scales: laboratory, field, and regional. Existing herbicide transport models will be used to determine the effect of individual or aggregate factors on the fate of atrazine in water. Models such as CREAMS will be

### Sources Of Pollution-Group 5B

used to evaluate the timing of pesticide movement while models such as PRZM and GLEAMS will be used to predict the importance of atrazine in the unsaturated zone. Geohydrologic information and factors relating to land use, climate, and soils will be stored in a Geographic Information System.

From these studies, regression models, multivariate. From these studies, regression models, multivariate statistical models will be developed to explain the patterns of atrazine contamination. (See also W91-11162) (Rubinstein-PTT)

APPLICATION OF THE DRASTIC MAPPING SYSTEM FOR EVALUATING GROUND WATER POLLUTION POTENTIAL IN OHIO. Ohio Dept. of Natural Resources, Columbus. Div. of Water.

R. J. Petty, and M. A. Hallfrisch.

IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 181-200, 6 fig, 2 tab, 4 ref, 3 map.

Descriptors: \*DRASTIC system, \*Geographic information systems, \*Groundwater pollution, formation systems, \*Groundwater pollution, \*Mapping, \*Maps, \*Nonpoint pollution sources, \*Ohio, \*Pollution index, Computer programs, Geohydrologic units, Groundwater movement, Land use, Optimization, Water use.

A pollution potential mapping program for Ohio has been developed under the direction of the Division of Water, Ohio Department of Natural Resources, using the DRASTIC mapping process. The DRASTIC system consists of two major elements the development of proceedings of the program of the pro ne DRASTIC system consists of two major ele-ments: the designation of mappable units, termed hydrogeologic settings, and the superposition of a relative rating system for pollution potential. Hy-drogeologic settings form the basis of the system and incorporate the major hydrogeologic factors which affect and control ground water movement. The factors are incorporated into a relative rank-tice and setting selection of the property of the pr ing and rating scheme to produce a DRASTIC index value that represents the relative pollution potential. Hydrogeologic settings are combined with the index to create units that can be graphi-cally displayed on maps. Demonstration mapping in Madison County, Ohio, resulted in a map with symbols and colors that illustrate areas of ground symbols and colors that linearity and a symbol water contamination vulnerability. The mapping program is being implemented on a county wide basis across the state according to specific selection criteria including availability of geologic and hydrogeologic data, groundwater usage, and land use within a county. The DRASTIC system optimizes within a county. The DRASTIC system optimizes the use of existing data to rank areas with respect to pollution potential. In Ohio, the system will be used to help direct investigations and resource expenditures and to prioritize protection, monitoring, and land use planning efforts. BIODEGRADATION OF HYDROCARBON VAPORS IN THE UNSATURATED ZONE. Massachusetts Univ., Amherst. Dept. of Civil En-

D. W. Ostendorf, and D. H. Kampbell.
Water Resources Research WRERAQ, Vol. 27,
No. 4, p 453-462, April 1991. 6 fig, 5 tab, 43 ref.
National Center for Groundwater Research and
Oklahoma State Universities Cooperative Agreement CR812808.

Descriptors: \*Biodegradation, \*Fate of pollutants, \*Hydrocarbons, \*Path of pollutants, Aeration zone, Groundwater pollution, Michigan, Military reservations, Soil contamination, Soil water, Solute transport, Traverse City. Volatilization

The widespread disposal of pesticides, herbicides, solvents, gasoline, heating oil, creosote, transmission fluid, and other hydrocarbons in waste lagoons, agricultural runoff, landfills, spills, and buried drum sites commonly leads to subsurface repulsion. The time-averaged concentrations of hypollution. The time-averaged concentrations of hydrocarbon and oxygen vapors were measured in the unsaturated zone above the residually contaminated capillary fringe at the U.S. Coast Guard Air Station in Traverse City, Michigan. Total hydro-carbon and oxygen vapor concentrations were observed over a 13-month period. Supplementary grain size, porosity, and moisture content data support the assumption of uniform, homogeneous site geology, which, in view of the planar hydrosite geology, which, in view of the planar hydro-carbon source term, abundant oxygen, and sparse data base, is suitable for simple analytical model-ing. In the assumed absence of advection, leaching, and transience, the analysis is a straightforward balance of gaseous diffusions and biological degra-dation coupled stoichiometrically in the two react-ing constituents. Volatilization is a significant transport mechanism for hydrocarbons at Traverse City, and biodegradation presents the second City, and biodegradation prevents the escape of appreciable contamination to the atmosphere for most locations at this site. Little oxygen is expect-ed to reach the water table because of the aerobic biodegradation process in the unsaturated zone. (Author's abstract)

Water Resources Research WRERAQ, Vol. 27, No. 4, p 463-477, April 1991. 13 fig. 3 tab, 86 ref. National Institute of Environmental Health Sciences Contract P42 ES043911-01 and NSF Grant

Descriptors: \*Groundwater pollution, \*Organic compounds, \*Path of pollutants, \*Soil contamination, Flushing, Hydrologic models, Mathematical models, Nonaqueous phase liquids, Numerical analysis, Solute transport.

Spills or leaks of organic chemicals to the environ-Spins or reass of organic chemicals to the environ-ment frequently result in the contamination of sub-surface soils and groundwater. Many of these pol-lutants are only slightly miscible in water and thus may exist as virtually immiscible or nonaqueous phase liquids (NAPLs). Migration of NAPLs in subsurface systems is complex. An attempt was made to assess the potential significance of devi-ations from local equilibrium for the exchange of mass between residual NAPLs and the aqueous phase in the saturated groundwater zone. A one-dimensional convection-dispersion mass balance equation incorporating a first-order interphase mass transfer rate relationship and temporal changes in blob configuration, was used to model this system. Analytical and numerical methods uns system. Analytical and numerical methods were employed to examine the steady state and transient behavior of the system under a variety of hypothetical aquifer conditions and pumping remediation schemes. Sensitivity of the model to several parameters, including mass transfer coefficient, blob size and shape, and Darcy velocity was explored. Results of this theoretical assessment indicate that nopeculibrium effects could alway a significant that no control the significant could be a significant to the control of the significant could be a significant to the significant control of the significant contro cate that nonequilibrium effects could play a significant role in some contamination scenarios, primarily for large blob sizes and relatively high ties. Design of soil flushing techniques will be impacted by these conclusions. Uncertainty in several parameter values used in this analysis indicate the need for further experimental investigation of this process. (Author's abstract)

SUBICE LAYERING AND ORIGIN OF ACIDIC WATERS IN A SMALL BOREAL LAKE DURING THE SPRING RUNOFF.

Institut National de la Recherche Scientifique, Sainte-Foy (Quebec).

J. Roberge, and H. G. Jones. Water Resources Research WRERAQ, Vol. 27, No. 4, p 479-492, April 1991. 12 fig, 24 ref.

Lake ice cover is a physical barrier that limits lakeatmosphere interactions. In a small boreal forest lake (Lac Laflamme, Quebec), the subice circula-tion of waters from five distinct origins (lake premelt water, lakeshore snowpack meltwater, ice cover meltwater, groundwater, and hillslope throughflow water) was studied during the spring melt period. A network of collared access holes was used to monitor the temperature, conductivity, and pH profiles of the water column beneath the ice cover. The study also included the tracing of snowbank meltwaters and through-flow waters with rhodamine. Conductivity and pH appeared to be efficient parameters for discriminating most of the water types considered. During the spring melt three distinct low-pH episodes were recorded in the lake outflow. The first episode (pH 5) occurred in the early melt period; snow and ice meltwaters layered beneath the ice forming a stratum approximately 20 cm thick. It moved toward the outlet under laminar flow conditions (observed velocity 1 m/hr). Two subsequent pH episodes of pH 5.3 and m/hr). Two subsequent pH episodes of pH 5.3 and 5.1 were observed during the massive melt period. These episodes were due to peak flows of hillslope throughflow, which entered the lake and formed a layer 20-40 cm thick in the water column (observed water velocity greater than 20 m/hr). The ice cover thus not only modified the nearshore water quality by inducing thermal layering, but strongly influenced the quality of the outflow waters due to the segregation and rapid evacuation of the throughflow and surface meltwaters. To reduce the complexity involved in analyzing solute transport, simplifying assumptions are employed. To work, these assumptions rely on the existence of 'ideal' transport. In real situations, however, 'nonideal' transport often occurs. An investigation was conducted of the capability of a model that explicitly accounts for multiple sources of nonequilibrium, to predict the transport of a nonequilibrium sorption-constrained solute in a instratified porous medium. Microaquifer experiments reported in the literature served as the source of the data that were analyzed. The best available information was used to identify values for all model input parameters, allowing the multi-process nonequilibrium (MPNE) model to be used

### Group 5B-Sources Of Pollution

in a predictive mode. The prediction obtained by the MPNE model provided a good description of the breakthrough curve obtained at a given velocithe breakthrough curve obtained at a given velocity. A breakthrough curve obtained at a slower velocity could be simulated when the apparent velocity dependence of the physical nonequilivelocity dependence of the physical nonequili-brium parameters was taken into account. Based on the reported results, the MPNE model seems to provide a valid representation of sorption dynamics and soluble transport for stratified systems in-fluenced by sorption capacity heterogeneity and multiple sources of nonequilibrium. The relative and combined impact of interlayer mass transfer, chemical nonequilibrium, and sorption capacity heterogeneity on the transport of a sorbing solute was elucidated. The MPNE has been used successfully to predict the nonideal transport of organic solutes at the field scale under both natural and induced gradients. (Author's abstract) W91-11239

STREAM CHEMISTRY IN THE EASTERN UNITED STATES: 1. SYNOPTIC SURVEY DESIGN, ACID-BASE STATUS, AND REGION-AL PATTERNS

Utah Water Research Lab., Logan.
P. R. Kaufmann, A. T. Herlihy, M. E. Mitch, and

Water Resources Research WRERAQ, Vol. 27, No. 4, p 611-627, April 1991. 9 fig, 3 tab, 69 ref. EPA Cooperative Agreements CR815168 and CR813061

Descriptors: "Acid rain, "Acid rain effects, "Acid streams, "Air pollution, "Data acquisition, "Surveys, "Water pollution sources, Acid neutralizing capacity, Aluminum, Eastern United States, Hydrogen ion concentration, Path of pollutants, Regional analysis, Spatial distribution, Sulfates, Water chemistry.

The extent and magnitude of surface water acidification caused by atmospheric pollution remains one of the most important and politically contro versial environmental issues of recent times. To assess the regional acid-base status of streams in the mid-Atlantic and southeastern United States, spring base flow chemistry was surveyed in a probability sample of 500 stream reaches representprobability sample of 500 stream reaches representing a population of 64,300 reaches (224,000 km). Approximately half of the streams had acid-neutralizing capacity (ANC) not exceeding 200 microequivalents/L. Acidic (ANC or e 0) streams were located in the highlands of the Mid-Atlantic region (southern New York to southern Virginia, 2300 km) in coastal lowlands of the Mid-Atlantic (2600 km) and in Florida (462 km). Acidic streams were rare (< 1%) in the highlands of the Southeast. Inorganic monomeric aluminum (Alim) concentrations were highest in acidic streams of the Mid-Atlantic highlands, where over 70% of the Mid-Atlantic highlands, where over 70% of the acidic streams had Alim > 100 micrograms/L, a concentration above which deleterious biological effects frequently have been reported. Dissolved organic carbon concentrations were higher in the lowland coastal streams compared with inland streams. The present data support a hypothesis that atmospheric sources and watershed retention conatmospheric sources and watershed retention con-trol regional patterns in streamwater sulfate con-centrations. Most stream watersheds retain the vast majority of the total nitrogen loading from wet deposition. The data also suggest, however, that some deposited nitrogen may be reaching streams in the Northern Appalachians. These results show that acidic surface waters are found outside the glaciated northeastern portions of the United States, and that watershed sulfate retention is not sufficient to prevent acidic conditions in some Mid-Atlantic Highlands streams. STREAM CHEMISTRY IN THE EASTERN UNITED STATES: 2. CURRENT SOURCES OF ACIDITY IN ACIDIC AND LOW ACID-NEUTRALIZING CAPACITY STREAMS.

TRALIZING CAPACITY STREAMS. Utah Water Research Lab, Logan. A. T. Herlihy, P. R. Kaufmann, and M. E. Mitch. Water Resources Research WRERAQ, Vol. 27, No. 4, p 629-642, April 1991. 7 fig, 3 tab, 39 ref. EPA Cooperative Agreement CR815168.

Descriptors: \*Acid neutralizing capacity, \*Acid streams, \*Surveys, \*Water pollution sources, Acid mine drainage, Acid rain, Acidity, Air pollution, Classification, Eastern United States, Florida, Forest watersheds, Hydrogen ion concentration, National Stream Survey, New Jersey, Nitrates, Organic matter, Regional analysis, Spatial distribution, Sulfates, Water chemistry.

The U.S. EPA conducted National Stream Survey (NSS) field activities in the eastern United States in the spring of 1986 as part of the National Surface the spring of 1986 as part of the National Surface Water Survey. Anion composition in NSS data was examined to evaluate the most probable sources of current acidity in acidic and low acid-neutralizing capacity (ANC) streams in the eastern United States. Acidic streams that had almost no organic influence (< 10% of total anions) and sulfate and nitrate concentrations indicative of evaporative concentrations of atmospheric deposi-tion were classified as acidic due to acidic deposition. These acidic streams were located in small (< 30 sq km) forested watersheds in the Mid-Atlantic highlands (an estimated 1950 km of stream length) an in the Mid-Atlantic coastal plain (1250 km). Acidic streams affected primarily by acidic deposition, but influenced by naturally occurring organic anions accounted for another 1180 km of organic anions accounted to another 1760 kin of acidic stream length and were located in the New Jersey Pine Barrens, plateau tops in the Mid-Atlantic and Southeastern highlands, and the Florida panhandle. The total length of streams acidic due paniature. The total legist of site and a sacrific was about the same as the total length of acidic streams likely to be affected by acid deposition (4380 km). Acidic streams whose acid anion composition was dominated by organics were located in Florida and the Mid-Atlantic Coastal Plain. In Florida, most of the acidic streams were organic dominated, whereas about half of the streams in the Mid-Atlantic Coastal Plain were organic dominated. Organicdominated acidic streams were not observed in the Mid-Atlantic and Southeast highlands. (See also W91-11241) (Author's abstract)

AIR QUALITY AND DEPOSITION OF TRACE ELEMENTS IN THE PROVINCE OF SOUTH-HOLLAND.

Dienst Centraal Milieubecheer Rijnmond, Schiedam (Netherlands).

Atmospheric Environment ATENBP, Vol. 25A, No. 3/4, p 691-698, 1991. 2 fig, 6 tab, 23 ref.

Descriptors: \*Air pollution, \*Deposition, \*Path of pollutants, \*The Netherlands, \*Trace elements, \*Water pollution sources, Cadmium, Cobalt, Emistrol, Lead, Trace metals

The air quality of the Rijnmond area of the prov-ince of South-Holland was measured in three campaigns to study trends in the trace element deposi-tion. In campaign A, year averaged values of a number of trace elements were measured in air samples for two locations, one close to the industrialized Rijnmond area and one 35 km to the north-east in the prevailing wind direction. In campaign B, the wet deposition of trace elements was measured using wet only rain gauges. In campaign C, rain samples were collected in southwesterly winds to quantify the portion of the Rijnmond emission in the wet deposition. In addition, the levels of trace elements in moss were analyzed to investigate how far the deposition of trace elements from the Rijnmond area and from a known source to the south-east of Rotterdam is detectable. Generally the levels of trace elements found in or near Rijnmond are higher than in the rural areas, though seldom statistically significant. When the wind direction is taken into account, it is possible to assess which sources and industrial areas contribute to the meassources and industrial areas contribute to the measured concentrations in the air. Higher levels are found downwind from the Rijmmond area for As, Cd, Co, Cr, Cu, Pb, Se, Sn, V and Zn. However, when the wind comes from the southeast, markedly high levels of Co, Cr, Se, and Sn are registered coming from the Belgian and other foreign industries. The deposition velocities in the Rijmmond area are rather low when compared to values measured elsewhere. It is theorized that the high frequency of rainfall could wash out the larger

particles with the bulk of the trace elements more efficiently and suppress resuspension. Concentra-tions of trace elements in moss were elevated near a scrap smelter that was not yet equipped with adequate dust filters. After the proper filters were added, the levels of trace elements in moss decreased. (Geiger-PTT) W91-11248

SEQUENTIAL SAMPLING OF PARTICLES, MAJOR IONS AND TOTAL TRACE METALS IN WET DEPOSITION.
University of East Anglia, Norwich (England). School of Environmental Sciences.

B. Lim, D. Jickells, and T. D. Davies

Atmospheric Environment ATENBP, Vol. 25A, No. 3/4, p 745-762, 1991. 12 fig, 14 tab, 41 ref.

Descriptors: \*Acid rain, \*Chemistry of precipita-tion, \*Ireland, \*Path of pollutants, \*Trace ele-ments, \*Trace metals, \*Wet deposition, Aerosols, Painfall Aluminum, Ions, Precipitation scavenging, Rainfall intensity. Silicon.

A precipitation event was sampled at a remote. A precipitation event was sampled at a remote, coastal site at Adrigole, Ireland, during May 1988. Major ions (Cl-, NO3-, SO4--, H+, Na+, K+, Ca++, Mg++) showed a rapid decrease in concentration with time, with the exception of emmonium and non-sea salt sulfate. Elements of marine origin (Cl-, SO4--, Na+, K+, Ca++ and Mg++) were positively correlated with each other (r = 0.97-1.00) but weakly correlated with each other transity. Total traces metal concentrations. rainfall intensity. Total trace metal concentrations (Al, Cd, Pb, Mn, Fe, Cu and Zn) decreased less rapidly than major ions. Single particle characterization of the insoluble matter identified Al and Si as the dominant elements and 0.2-0.4 microns diameter as the median size range. Selective removal mechanisms of aerosols associated with minor and major elements include removal by below cloud processes and scavenging by within cloud mechanisms. (Author's abstract)

MAJOR IONS IN MARINE RAINWATER WITH ATTENTION TO SOURCES OF ALKA-LINE AND ACIDIC SPECIES,

Atmospheric Environment ATENBP, Vol. 25A, No. 3/4, p 763-770, 1991. 5 fig, 4 tab, 12 ref.

Descriptors: \*Acid rain, \*Chemistry of precipita-tion, \*Ion transport, \*Ions, \*Path of pollutants, \*Water pollution sources, Air masses, Calcite, Hy-drogen ion concentration, Neutralization, Nitric acid. Salts. Sulfuric acid.

Rainwater was collected in ultra-clean conditions during three field experiments (two on Corsica and one during a North-South Atlantic transect of the 1988 Polarstern cruise). This rainwater was imme-1988 Polarstern cruise). This rainwater was immediately filtered and the major ions were measured by ionic chromatography, atomic absorption and colorimetric methods. In these marine areas, the concentrations of major ions range over one or two orders of magnitude and are generally dominated by the redissolution in rainwater of the sea salts. The non-sea salt component shows the presence of anthropogenic nitric and sulfuric acids which are well correlated with the origin of the air masses and which lead to acidic raise (nH from 4 masses and which lead to acidic rains (pH from 4 to 5). High values of pH (6-7) are also observed and can be explained by the neutralization of strong acids by natural alkaline dusts such as calstrong acids by natural alkaline dusts such as cal-cite, which are mainly transported from the desert areas of the African continent. A study of these variations in major ion compositions in relation to three-dimensional, air-mass trajectories demon-strates the behavior of these two components during African dust transport. MODELLING THE ATMOSPHERIC TRANSPORT OF TRACE METALS INCLUDING THE ROLE OF PRECIPITATING CLOUDS.

### Sources Of Pollution—Group 5B

GKSS - Forschungszentrum Geesthacht G.m.b.H., Geesthacht-Tesperhude (Germany, F.R.). L. Levkov, D. P. Eppel, and H. Grassl. Atmospheric Environment ATENBP, Vol. 25A, No. 3/4, p 779-789, 1991. 7 fig, 31 ref.

Descriptors: \*Cloud chemistry, \*Cloud physics, \*Lead, \*Model studies, \*Path of pollutants, \*Trace metals, Aerosols, Air pollution, Mathematical models, Microphysics, Particle size, Precipitation

The wet removal of atmospheric lead was studied using a three-dimensional mesoscale model with parameterized microphysics of clouds and precipi-tation that was extended to include wet scavenging iation that was extended to include wet scavenging and deposition of trace metals from the atmosphere. Simulations were carried out in a domain of 400 sq km in the southeastern part of the North Sea including many clouds in various stages of development. The model assumes that the particles acting as host for the lead particles are cloud condensation nuclei (CCN) calculated in the model as part of aerosol particles in the air. The variation of the average concentration of aerosol particles with height as a function of size is based on data given previously. Both calculated flong range with height as a function of size is based on data given previously. Both calculated (long range transport model) and measured atmospheric monthly mean concentration of lead at the German coast of North Sea and Baltic Sea given by other researchers are used as an input pollution level by calculation of the vertical profile of the initial mean mass lead concentration in the air. The lead is accounted to be distributed uniformly to the lead. mean mass lead concentration in the air. In elean is assumed to be distributed uniformly on the aerosol particles, and the vertical profile of the initial 
mass concentration of lead in the air is assumed to 
be proportional to the vertical profile of number of 
aerosol particles as a function of size with height. 
In other words, the model deals with the fraction of lead which can enter cloud water mainly through nucleation scavenging (in-cloud scaveng-ing or rainout). The calculated concentration of ing or rainout). The calculated concentration of lead in rainwater at the first model layer (50 m above the sea surface) is in good agreement with measured weekly averages of lead deposition fluxes during precipitation events on the island of Pellworm in the vicinity of the model domain selected for validation of the numerical model. DISTRIBUTION AND MIGRATION OF HEAVY METALS IN THE ENVIRONMENT OF THE ALTAI MOUNTAINS IN CONNECTION WITH ECOLOGICAL SUBSTANTIATION OF THE KATUN HYDROELECTRIC STATION PROJECT.

1. L. Dmitrieva, Y. V. Zelyukova, V. S. Boldenkov, and I. V. Vezlutskaya. Hydrotechnical Construction HYCOAR, Vol. 24, No. 6, p 405-410, December 1991. 2 fig, 5 tab, 11 ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 6, pp. 35-38, June, 1990.

Descriptors: \*Environmental impact, \*Heavy metals, \*Hydroelectric plants, \*Reservoir construction, \*Soviet Union, \*Water pollution sources, Altai Mountains, Antimony, Arsenic, Cadmium, Chromium, Copper, Fish, Katun Hydroelectric Station, Lead, Mercury, Nickel, Teletskoe Lake, Tissue analysis.

The construction of the Katun hydroelectric station in the Kuznetsk-Altai polymetallic belt (Soviet Union) has been proposed. The current content of mercury and other heavy metals in various components of the environment was examined in the Altai mountains, possible sources of entry of mercury into the Katun reservoir were determined, and the ecological risk associated with the creation of this reservoir was evaluated. The content of mercury in the waters of the Katun is 5-10 times below the maximum allowable concentration below the maximum allowable concentration (MAC = 0.5 microgram/l). Besides mercury, 23 trace elements were identified in the surface waters of the Altai Mountains. In the Katun water in the hydrostation construction reach, an excess beyond the MAC was observed for copper (1.7 MAC) and chromium (2.1-3.6 MAC). This is due to the natural background of the region. The levels of aquatic arsenic, antimony, cadmium, lead, and nickel is considerably below the MAC. The mercury con-

tent in tissues of 10 fish species of the Altai Mountains was examined (452 samples). The accumulation of the element was determined to a great extent by the fish's feeding habits, with levels for plankton feeders in the range 0.003-0.08 mg/kg, for plankton feeders 0.05-154 mg/kg, and for predators 0.07-0.254 mg/kg. An excess of the MAC was observed in several cases for predatory fishes caught in Teletskoe Lake (2% of the entire catch). The sources of entry of mercury and other heavy The sources of entry of mercury and other heavy metals into the planned reservoir are the water discharge and sediment load of the Katun, subsurface waters, and soils of the zone of flooding; some increase in the mercury concentration (not greater than the MAC) should be expected in the first 1-3 yr after filling. As the bed soils are flushed, this level will decrease. The metallogenic conditions in this area do not appear serious enough to prevent the creation of the hydrostation and reservoir. Fenitrothion (O,O-dimethyl O-4-nitro-m-tolyl phosphorothioate) has been the chemical of choice in spray programs directed at forest defoliators in New Brunswick, Canada for over twenty years. A study was conducted to determine the contaminastudy was conducted to determine the contamina-tion of small ponds by forestry insecticides during operational spray programs in order to assess the exposure to lentic biological systems. Six ponds were selected within operational spray blocks of were selected within operational spray blocks of the 1989 spruce budworm spray program in New Brunswick. All blocks were sprayed with a water solution containing 11.0% fenitrothion, with a nominal application rate of 210 g active ingredi-ent/ha. Measured deposits of fenitrothion on filter paper after spray ranged from 24.3 to 0.7 mg/sq m, while mean deposits ranged from 17.6 mg/sq m on Pond 1 after the first spray event to 1.2 mg/sq m on Pond 1 after the second spray event. Mean surface water concentrations ranged from 1.5 mg/ L on Pond 2 after the first spray event to 0.04 mg/ L on Pond 5 after the second spray event. The maximum mean surface water concentrations ob-served are within the range of fenitrothion 96-hour served are within the range of fenitrothion 96-hour LC50's for salmonid fish. However, maximum surface water concentrations are rapidly attenuated due to dilution and degradation. Residue concentrations in outflow water are representative of well-mixed water column concentrations and were much lower than the surface concentrations of the ponds they drained. In some cases however, they exceeded the 20 micrograms/L threshold for lotic benthic invertebrate impact calculated in another study. The impact of forestry use of fenitrothion on benthic invertebrates in small ponds may be substantial and should be determined. (VerNooy-PTT W91-11298

TRANSPORT OF THE FUNGICIDE CHLOR-OTHALONIL FROM ITS OPERATIONAL USE ON A POND ECOSYSTEM. Inland Waters Directorate, Moncton (New Bruns-wick). Water Quality Branch.

H. J. O'Neill.

Bulletin of Environmental Contamination and Toxicology BECTA6, Vol. 46, No. 6, p 822-828,

June 1991. 3 fig, 7 ref.

Descriptors: "Chlorothalonil, "Fungicides, "Organochlorine pesticides, "Path of pollutants, "Ponds, "Spraying, "Water pollution sources, Chemical analysis, Hazard assessment, Pesticide residues, Pesticide toxicity, Sediment sampling,

Chlorothalonil (tetrachloro isophthalonitrile) is a fungicide used extensively in the Maritime Provinces of Eastern Canada to combat potato blight. A small watercourse on Prince Edward Island, known locally as the Cape Transverse River, was selected in the spring of 1989 as an appropriate location for concurrent field studies into the translocation for concurrent field studies into the transport and aquatic effects of chiorothalonii. The study site centered upon a small pond (0.2 ha) and sampling stations were established 0.75 km upstream of the pond, at the pond inlet, and 30 m downstream from the pond outlet. At each site, water, bottom sediments and sediment trap materials were collected before and after each of two agril overgravings. The hours perturbed the conas were collected before and after each of two aerial oversprayings. Ten hours post-spray the con-centration of chlorothalonil in whole water was observed to be 1.9 micrograms/L. However, for a period of up to 1.5 hours post-spray the mass of chlorothalonil on the suspended sediment fraction remained above 10 micrograms. After the second overspray, a maximum concentration of 365 micro-grams/L was observed at the outlet at 30 minutes grams/L was observed at the outlet at 30 mnutes post-spray, while a maximum of 452 micrograms/L was recorded at 25 minutes post-spray at the downstream location. Sediment trap materials and bottom sediments collected pre and post-spray at the upstream, inlet and downstream sites were all less than the analytical detection limit (0.004 mg/ kg). The maximum observed post-spray concentra-tion of 452 micrograms/L was above the estimated LC50 for bluegill sunfish, rainbow trout and channel catifish. Concentrations greater than 250 micrograms/L would have been sustained for 1.5 to 2 hours, under the operational conditions and stream flows encountered. Data from the first overspray indicate that chlorothalonil concentrations would have exceeded reported LC50 values for approxi-mately 4.5 hours. (VerNooy-PTT)

CONCENTRATION OF METALS IN VARIOUS LARVAL STAGES OF FOUR EPHEMEROP-TERA SPECIES.

Springborn Labs., Inc., Wareham, MA. K. M. Jop.

R. M. 30p.

Most of the surface waters in the southern part of Poland have received considerable amounts of wastewaters. Some of the industrial wastewaters contain a large amount of metals which ca biologically active, toxic or have a potential for bioconcentration. In this study, mayflies were sam-pled from the lowland stream Lane Bloto in the poloconcentration. In this study, mayrines were sampled from the lowland stream Lane Bloto in the Niepolomice Forest located near Krakow (South Poland). They were collected twice monthly over one year from the sediment and plants. Concentrations of cadmium (Cd), lead (Pb), copper (Cu) and carric (Zn) in whole bodies of the various size groups of the four mayfly species found were determined. The following mean annual concentrations (in micrograms/L) were recorded in water: 1 microgram Cd/L, 17 micrograms Pb/L, 30 micrograms Cd/L, 197 micrograms Pb/L, 30 micrograms Cd/L, 197 micrograms Pb/L, 30 micrograms Cd/L, 197 micrograms Ca/L, 193 mg Cd/L, 193 mg Cd/L, 193 mg Cd/L, 194 mg Cd/L, 194 mg Cd/L, 194 mg Cd/L, 195 mg Pb/L, 26 mg Cu/L, 193 mg Cd/L, 164 mg Cd/Pb/Cu/Cd/L, Results suggest that the exposure time for mayflies is not critical in bioconcentration of metals, i.e., Baetis vernus in 4 months accumulated as much as Leptophlebia vespertina in accumulated as much as Leptophlebia vespertina in 10 months. Also, colonization seems to be important in relation to the concentration of selective

### Group 5B-Sources Of Pollution

metals. The concentration of Cu was similar, while Cd, Pb, and Zn were slightly different in two burrowers, Ephemera dancia and E. vulgata. E. dancia was found primarily in a sandy bottom with low organic matter, while E. vulgata colonized sediments rich in organic matter. The concentrasediments from in organic matter. The concentra-tions of all measured metals decreased in consecu-tive larval stages of all four species, particularly prior to emergence. Because the concentrations of metals in whole body is regulated by physiological processes and varies substantially during the lifeprocesses and varies substantially during the ine-cycle, mayflies are of no value for biological moni-toring of metals unless the monitoring program includes their complete life cycle to account for differences in the relative metal concentration of instar stages. DISTRIBUTION OF FECAL POLLUTION IN-DICATOR BACTERIA IN LAKE KINNERET. Kinneret Limnological Lab., Tiberias (Israel). T. Bergstein-Ben Dan, and L. Stone. Water Research WATRAG, Vol. 25, No. 3, p 263-270, March 1991. 4 fig, 7 tab, 21 ref.

Descriptors: \*Bioindicators, \*Fecal bacteria, \*Israel, \*Jordan River, \*Lake Kinneret, \*Path of pollutants, \*Wastewater pollution, \*Water pollution sources, Distribution patterns, Enteric bacteria, Influent water, Sedimentation, Statistical anal-

Lake Kinneret is the only natural fresh water lake in Israel and supplies 33% of the country's total water requirement. The lake is also heavily used for recreation and as a source of commercial fish-ing. The Jordan river enters Lake Kinneret at the north and provides 66% of the total water entering the lake. The Jordan also brings with it sewage from Upper Galilee, mainly during the winter floods, and is a major source of pollution to the lake. The distribution of fecal indicator bacteria in Lake Kinneret has been monitored closely over depth and time for a 1 year period along the river flow through the lake. It is apparent that factors including the Jordan River inflow rate, and sedimentation, were partly responsible for these distri-butions. Statistical analysis found the Jordan's inflow rate significantly correlated with bacterial densities at the lake's inlet. An examination was also made of the partitioning of fecal indicator bacteria between surface waters, bottom waters, and sediments in the lake. The data shows that bacterial numbers are always higher in the bottom waters than at the surface at all distances from the inlet. The partial disappearance of the enteric bac-teria was therefore due to sedimentation which proves to be an important factor in the vertical distribution of bacteria. The effects of light, dilution, H2S concentration and mortality were also found to contribute to some extent. Each bacteria in the surface water showed a different disappearance rate. The study has made clear the need assess the effects of these other contributing facassess the effects of these other contributing fac-tors. Each bacterial species has its own specific survival rate and unique response characteristics that determine its distribution over depth and time. (Doyle-PTT) W91-11322

DISTRIBUTION OF CHLOROBENZENES IN THE BOTTOM SEDIMENTS OF ISE BAY. National Research Inst. for Pollution and Resources. Yatabe (Japan).

S. Masunaga, Y. Yonezawa, and Y. Urushigawa. Water Research WATRAG, Vol. 25, No. 3, p 275-288, March 1991. 11 fig, 2 tab, 10 ref.

Descriptors: \*Chlorinated aromatic compounds. Pescriptors: "Cnornated aromatic compounts, \*Fate of pollutants, "Ise Bay, "Path of pollutants, \*Sediment contamination, Adsorption-desorption, Distribution patterns, Japan, Particle size, Sedi-ment sampling, Sediment-water interfaces, Suspended sediments, Suspended solids.

The concentrations of dichloro-, to hexachlorobenzene in the surficial bottom sediments in Ise Bay, Japan, were determined as a preliminary study of the behavior of these compounds in this coastal environment. The sediment samples were collected from 10 stations on the west coast and in Yokkai-chi Port in March 1987 and from 44 stations all ort in March 1987 and from 44 stations ail over the bay in October 1987. 1,2-, and 1,3-Dichlorobenzene, and 1,2,3-, and 1,2,4-trichlorobenzene levels were highest in the vicinity of Yokkaichi Port and Tsu-Matsuzaka Port. Higher levels of these compounds were also found in the middle of these compounds were also round in the induce of the bay. The concentrations of tetrachlorobenzene isomers were generally low but they were also higher in the vicinity of the two ports. 1,3,5-Trichlorobenzene was higher only in the vicinity of Yokkaichi. The levels of these compounds were not higher around Nagoya City, the largest city in the bay. The stations with higher dichloro-, and trichlorobenzenes concentrations in the middle of the bay covered the area where sediment particle size was small. This was also the area where downward water flow was estimated to exit. These findings indicated that these congeners were adsorbed by suspended particulates and transported by water flow. The distribution patterns, therefore, could be explained by the following effects: the distance from the source, the horizontal transport caused by the river inflows and the sedimentation caused by downward water flow. Pentachlorobenzene concentration was very low and its distribu-tion was not clear. Hexachlorobenzene had quite a different distribution pattern from other congeners, indicating that its sources were different. (See also W91-11325) (Author's abstract) W91-11324

BEHAVIOR OF CHLOROBENZENES IN ISE BAY, ESTIMATED FROM THEIR CONCENTRATIONS IN VARIOUS ENVIRONMENTAL MEDIA.

National Research Inst. for Pollution and Re-

S. Masunaga, Y. Urushigawa, and Y. Yonezawa. Water Research WATRAG, Vol. 25, No. 3, p 289-297, March 1991. 7 fig, 2 tab, 13 ref.

Descriptors: \*Chlorinated aromatic compounds, \*Fate of pollutants, \*Ise Bay, \*Path of pollutants, Adsorption-desorption, Distribution patterns, Industrial wastewater, Japan, Model studies, Sediment contamination, Sediment-water interfaces,

Field survey of pollutants in various environmental media is indispensible for modeling the behavior of organic compounds discharged into the coastal environment. In this study, the concentrations of chlorobenzenes were measured in Ise Bay where industrial wastewater enters. Some chlorobenzene congeners, 1,3-dichlorobenzene and 1,2,4-trichlorobenzene, were detected in seawater, suspended particulate and bottom sediment samples and their behavior was analyzed. The horizontal distribu-tions showed that these chlorobenzene concentrations in the surface water and sediments were higher in the area near the shore of the industrial area than in the offshore area. The soluble chloro-benzene concentrations in the bottom water were low at all stations. The vertical distribution survey at each sampling site showed that the soluble con-centrations were high in the surface water and low in the bottom water, but that those in the suspend-ed particulates and the bottom sediments (dry solid base) had relatively similar concentrations. This indicated that chlorobenzenes in the bottom suspended particulates and in the bottom sediments were not equilibrated with chlorobenzenes in the bottom seawater. This could be explained by the following chlorobenzene behavior: the chlorobenzenes were adsorbed by suspended particulates in

the surface water and settled to the bottom swiftly through less polluted seawater in the lower water layer with little desorption. This caused the chlor-obenzene concentration gradient in the bottom sediment which reflected the chlorobenzene concentration adsorbed by suspended particulates in the surface water. The behavior of chlorobenzenes suggested in this study showed that the use of chemical fate models based on the assumption that the soluble fraction and the fraction adsorbed by suspended particulates are always in equilibrium may yield misleading results. A study was made of the occurrence of inorganic tin and methyl-butyltin and n-butyltin compounds in water and sediments of the Rhine river. Speciain water and sediments of the Rhine river. Specia-tion was performed by volatilization of the tin species as the corresponding hydrides, separation on a chromatographic packing material, and detec-tion by atomic absorption spectrometry. Sediments were extracted by refluxing in a methanol/HCI solution. The analysis of the Rhine water samples showed dimethyltin, monobutyltin, and dibutyltin to be present in the low ppt range. The Rhine sediments contained methyl-butyltin and butyltin compounds in the mid ppb range. High concentra-tions of tributyltin were found in samples from harbor locations. The contributions of the various sources to the overall input of methyl-butyltin and butyltin compounds into the Rhine are believed to come from the effluents from municipal sewage plants. PATHWAYS OF SILVER UPTAKE AND TROPHIC TRANSFER IN ESTUARINE ORGA-NISMS.

Academy of Natural Sciences of Philadelphia, Benedict, MD. Benedict Estuarine Research Lab. D. B. Connell, J. G. Sanders, G. F. Riedel, and G.

Environmental Science and Technology ESTHAG, Vol. 25, No. 5, p 921-924, May 1991. 2 fig, 2 tab, 28 ref.

Descriptors: \*Estuaries, \*Food chains, \*Marine organisms, \*Path of pollutants, \*Silver, Chemical speciation, Diatoms, Dissolved solids, Estuarine sediments, Geochemistry, Shrimp, Trophic level.

Recent evidence has suggested that the uptake of Ag by some aquatic organisms occurs from Ag dissolved in the water column, and not through uptake from Ag-contaminated phytoplankton or particles. In addition, it has also been shown that Ag may bind quite strongly to algal cells thus making Ag unavailable to herbivores. One series of making Ag unavailable to networks. One series of experiments were performed to investigate the mechanisms controlling Ag uptake by the grass shrimp, Palaemonetes pugio. The shrimp were exposed to elevated Ag either dissolved in the water column or associated with planktonic or detrital

### Sources Of Pollution-Group 5B

food particles. The shrimp were fed 10% of their food particles. The shrimp were fed 10% of their body weights for 4-6 hours on a daily basis. The results of the investigation revealed that P. pugio rapidly incorporated Ag dissolved in brackish water in proportion to its concentration, but did not incorporate significant quantities of Ag from the food sources containing elevated Ag contents. In another set of experiments, Ag uptake and retention was investigated in the centric diatom, Thalassiosira weissflogii. The outcome of the experiments showed that, once incorporated, Ag remained tightly bound to the cell membrane, even after cells were disrupted by sonication, leached at mained tightly bound to the cell membrane, even after cells were disrupted by sonication, leached at low pH, or treated with digestive enzymes. Thus, the acts of feeding and digestion by invertebrates are not likely to dislodge Ag from biotic particles and food-borne transfer of Ag within aquatic food chains is unlikely to occur. Geochemical controls over dissolved silver speciation and bioavailability are much more important in determining Ag incorporation. (Korn-PTT) W91-11337

BIOCONCENTRATION OF CHLORINATED AROMATIC HYDROCARBONS IN AQUATIC MACROPHYTES.

Because of their limited mobility, their abundance in many aquatic systems, and their potential to sorb organic substances, aquatic macrophytes have the potential to function as in situ biomonitors of waorganic substances, aquatar mastrophytes have the potential to function as in situ biomonitors of waterborne contamination. A set of experiments were conducted to investigate the bioconcentration and the uptake and elimination kinetics of a series of nonreactive, hydrophobic organic substances investigated in the submerged aquatic macrophyte, Myriophyllum spicatum. The substances selected covered a wide range of aqueous solubilities and octanol-water partition coefficients (Kow). The results of the experiments revealed that the plantwater bioconcentration factor followed a linear relationship with the octanol-water partition coefficient for all chemicals. In addition, the uptake and elimination rate constants tended to follow a 'biphasic' relationship with Kow. The experimental calculations illustrate that chemical bioconcentration may have a significant effect on the distribution and dynamics of hydrophobic organic substances in aquatic systems. Extruded brine, generated during sea ice formation in nearshore arctic waters, can sink to the bottom and form a stable bottom boundary layer. This layer can persist for periods of up to 4-6 months. Limited quantities of dissolved aromatic hydrocarbons resulting from a spill of crude oil or refined petroleum distillate products during periods of ice growth then can be transported as conservative components to the benthes with sinking brine. components to the benthos with sinking brine. Once incorporated into the stable bottom boundary layer, these aromatic components are no longer Ty layer, tries a domain components are no long-subject to loss by evaporative processes, and they only can be diluted by ultimately mixing with uncontaminated water masses, a process that pro-ceeds slowly throughout the ice-covered period. This mechanism for the transport of dissolv Inis mechanism for the transport of dissolved ny-drocarbons has been demonstrated through labora-tory test-tank simulations and a chemical/physical oceanographic field program conducted in the Chukchi Sea near Pt. Franklin, AK in March 1985. The results demonstrate a mechanism by which a spill of crude oil or refined products in a refreezing lead system could result in elevated concentrations of dissolved aromatics in bottom waters. Potential of dissolved aromatics in bottom waters. Potential problems with extrapolation of the results from this experiment to an actual oil spill would involve consideration of the type and volume of oil (or petroleum product) spilled, the degree of weathering of the oil prior to mixing with brine, the duration of the ice (brine) formation process, and the degree of water column density stratification and depth. 2,3,7,8-Tetrachlorodibenzo-p-dioxin (2,3,7,8-TCDD) was measured in sediments and suspended matter samples from estuaries adjacent to an industrial site in Newark, N.J., where chlorinated phenois had been produced. Present day and recent historical levels of 2,3,7,8-TCDD contamination were established through the use of radionuclide time tracers (7Be, 137Cs). Concentrations up to 21,000 parts per trillion (ppt) were found in sediments deposited near the site. Pre-1950 production of DDT at the same industrial site provided another sensitive pollutant source tracer. The total deposition of 2,3,7,8-TCDD in Newark Bay sediments since the late 1940s has been approximately 4-8 kg, among the largest releases documented to 4-8 kg, among the largest releases documented to date. Sediments dredged from estuaries in this date. Sediments dredged from estuaries in this region have been disposed of on land surrounding Newark Bay and at a coastal ocean dumpsite. The current practice of subaqueous disposal of sediments dredged from these waters at a coastal ocean dump site provides for the significant and perhaps dominant transport of 2,37,8-TCDD to the continental shelf of the northeastern United States. A series of phenyltins and butyltins were deter-mined in the water column, sediment, and biota of

two freshwater marinas of Lake Lucerne, Switzertwo freshwater marinas of Lake Lucerne, Switzerland. Considerable concentrations of triphenyltin (TPT), diphenyltin (DPT), and monophenyltin (MPT) were found for the first time in all the compartments. In addition, tributyltin (TBT), dibutyltin (DBT), and monobutyltin (MBT) occurred in significant concentrations. During the period 1985-1990, aqueous TBT concentrations followed a seasonal pattern with increases of up to 752 ng/L in late sering followed by a successive decrease. in late spring, followed by a successive decrease until winter, when concentrations remained around 100 ng/L. TPT and TBT concentrations decreased ItO ng/L. IPI and IBI concentrations decreased during the observation period. Of the total aqueous TBT, 95-99% was present in the dissolved phase. In the mussels, Dreissena, TPT and TBT residues ranged up to 3.88 and 9.35 micrograms/g, respectively. Vertical sediment core profiles showed the highest TPT and TBT concentrations of up to 107 and 2043 micrograms/g, respectively, in the top highest TPT and TBT concentrations of up to 107 and 2043 micrograms/kg, respectively, in the top with decreasing values with depth. Dating of the core and the ocurrence of only low concentrations of DBT and MBT indicate that TBT is conserved in these sediments over a time period of years. (Author's abstract) W91-11342

ELECTROLYTIC MODEL SYSTEM FOR REDUCTIVE DEHALOGENATION IN AQUEOUS ENVIRONMENTS.

Stanford Univ., CA. Dept. of Environmental Engi-

C. S. Criddle, and P. L. McCarty.

Environmental Science and Technology ESTHAG, Vol. 25, No. 5, p 973-978, May 1991. 8 fig. 4 tab, 48 ref. U. S. National Science Founda-tion Grant ECE-8519243.

Descriptors: \*Aquatic environment, \*Biodegrada-tion, \*Chlorinated hydrocarbons, \*Dehalogena-tion, \*Electrolysis, \*Fate of pollutants, \*Water pol-lution treatment, Carbon dioxide, Carbon monoxide, Chemical reduction, Chlorides, Dichlorometh-ane, Electrochemistry, Formate, Hydrolysis, Mi-crobial degradation, Tetrachloromethane, Trichlo-romethane, Wastewater treatment.

Tetrachloromethane (CT) is transformed in biological systems via two major pathways: hydrogeno-lysis to trichloromethane (CF) and hydrolysis to carbon dioxide. The mechanism of hydrolysis is poorly understood. One possibility is a hydrolytic reduction of CT to formate or carbon monoxide followed by oxidation to carbon dioxide. In biologfollowed by oxidation to carbon dioxide. In biological systems, formate and carbon monoxide are readily oxidized to carbon dioxide, making their identification difficult, but in an electrolysis cell, reduction is physically separated from oxidation, and the production of formate and carbon monoxide at a cathode can be observed. Measurements of current, chloride, CF, dichloromethane, formate, and CO upon electrolysis of CT in aqueous solution supported the conclusion that hydrogenolysis to CF and hydrolytic reduction to CO and formate are significant and competitive reductive processto Cr and nytoryte reduction to Co and formate are significant and competitive reductive process-es. Similar findings were obtained for the reduction of 1,1,1-trichloroethane via hydrogenolysis to 1,1-dichloroethane and to an unidentified dechlorinatdefinition that is a two-level to the continuation of the pathway. It is suggested that electrolysis in aqueous environments may have value as a useful tool for the understanding and control of reductive dehalogenation and as a novel treatment technology. zenes, Chemical interactions, Chlorinated solvents, Dechlorination, Michigan, Microbial degradation, Tetrachloroethylene.

Chlorinated solvents are among the most common industrial contaminants of groundwater and are industrial containmants of groundwater and are followed closely in importance by alkylbenzenes. Tetrachloroethene (PCE) is resistant to aerobic biodegradation. However, it is occasionally reductively dechlorinated in anoxic contaminated aquifers. This is particularly true if the subsurface also contains other organic compounds that can serve as electron donors and whose utilization by subsurface bacteria will deplete the available oxygen. Recent studies suggest that certain alkylbenzenes (e.g., toluene) could potentially serve as electron donors for the reductive dechlorination of PCE. The biologically mediated interactions of release the official mediated interactions of toluene and PCE under anaerobic conditions were investigated by using incubated microcosms spiked with PCE and toluene. These microcosms were constructed with aquifer solids from an area that was exposed to both alkylbenzenes and chlorinated ethenes at a site in Michigan. The overall results of the study indicated that toluene could act as an initial source of reducing potential for the reductive dechlorination of chloroethenes under anaerobic conditions. In addition, the cultivation of this consortium from a site impacted by alkylbenzenes and chloroethenes is an indication that this process may occur in contaminated aquifers. (Korn-PTT) W91-11344

## SHEEP-DIPS AS A SOURCE OF POLLUTION OF FRESHWATERS: A STUDY IN GRAMPIAN

Grampian Regional Council, Aberdeen (Scotland).

Grampian Regional Council, Abertoeen (Scotland). Dept. of Water Services.

During 1984-1985 freshwater samples taken from the whole catchment of the River Ugie were anathe whole catchment of the River Ugie were analyzed for levels of organochlorine and organophosphorus pesticides and levels of phenolic compounds. The concentrations of alpha-BHC, gamma-BHC, dieldrin, o.p-DDT, p.p-DDT and p.p-DDE were initially at or below the limits of detection of the analytical techniques used and were well below the maximum admissible concentrations (MAC). However, during July and August of 1984, gamma-BHC levels were found in significant concentrations at Balmoor suggesting contents of the supplementations at Balmoor suggesting concant concentrations at Balmoor suggesting con-tamination of river water by sheep dip. Diazinon, propetamphos and fenchlorphos, also found in sheep dip were found in only a few of the catchment samples at concentrations exceeding 100 nan-ograms/L. Chlorfenvinphos was found throughout the catchment with concentrations exceeding 3000 nanograms/L in some of the samples. Phenolic compounds in rivers adjacent to sheep dipping compounds in rivers adjacent to sheep dipping areas were low enough as to warrant no immediate concern. A sheep-dip tank sited, constructed, and managed according to Ministry of Agriculture, Fisheries and Food guidelines would not pose a major source of pollution for a large receiving river. Descriptors: \*Dieldrin, \*Endosulfan, \*Jamaica, \*Path of pollutants, \*Pesticides, Chemical properties, Degradation, Hydrolysis, Kinetics, Photolysis, Tropical regions, Volatility.

The importation of pesticides into Jamaica has doubled in the past ten years. This has created a need for scientific data on the environmental fate of these pesticides in tropical agroecosystems. Kinetic studies on the degradation of three common-ply used pesticides in Jamaica, dieldrin, alpha, and beta-Endosulfan, were carried out under laboratory conditions that simulated those tropical agroe-cosystems. Studies included measurements of the rate of volatilization, hydrolysis, and photolysis. Volatility from electron capture (EC) formulations on glass surfaces at 30 C was in the order of alphaon glass surfaces at 30 C was in the order of alpha-Endosulfan > dieldrin > beta-Endosulfan. Kinetic data provided first order plots of ln F vs t with correlation coefficients ranging from 0.99 to 0.85 (F is the volatilization flux expressed in micro-grams/sq cm/day and t is the time in days) and half life values ranging from 2 to 7 days. Hydroly-tic degradation rates of both alpha and beta-Endo-sulfan at 30 C decreased with pH in the sequence ( half life = 0.04 days) > pH 7.0 (half life= 25 days) > 4.5 (half life= 90 days) for a first order model. Hydrolysis of dieldrin (half life= 95 days) was insensitive to pH over the same range. Photo-lytic degradation followed a first order model and the half lives were in the order dieldrin (2.5 h) < beta-endosulfan (3.5 h) , alpha-endosulfan 920 h) in hexane solution and dieldrin (1.7 h) < beta-endo-sulfan (3.3 h) < alpha-endosulfan (48 h) in aquecus solution. Photolysis rates in sunlight were in the solution. Photolysis rates in sunlight were in the same order, but half lives were between 20 and 40 days in bulk hexane solution, while average half life was 15 h for each compound in a thin layer hexane solution. AQUEOUS PHOTOLYSIS OF NAPROPA-

MIDE. ICI Americas, Inc., Richmond, CA. Agricultural

L. L. Chang, B. Y. Giang, K. Lee, and C. K.

Tseng. Journal Journal of Agricultural and Food Chemistry JAFCAU, Vol. 39, No. 3. p 617-621, March 1991. 6 fig, 1 tab, 12 ref.

Descriptors: \*Degradation products, \*Fate of pol-lutants, \*Herbicides, \*Napropamide, Chemical properties, High performance liquid chromatogra-phy, Mass spectrometry, Nuclear magnetic reso-nance, Photolysis.

Napropamide is the active ingredient in Devrinol, a preemergence herbicide for controlling weeds in certain fruit and nut crops. The photolysis rate of napropamide in water was determined and the degradation products formed were identified and degradation products formed were identified and quantified in order to assess the environmental impact posed by the use of napropamide. Photolysis of napropamide was examined at 25 C in aquestion of the propagation of the propagation of the propagation of the dark, napropamide degraded rapidly upon irradiation with simulated light. The pseudo-first-order photolysis half-life and rate constant were 5.7 min and 0.127 min, respectively. Three major photodegradation products were produced in yields up to 20%, 27% and 9%. The three photodegradation products were isolated by high performance liquid chromatography (HPLC) and their structures identified by nuclear magnetic restinance (NMR) and mass spectrometry. The mass spectral data suggested that two of these are isomers of napropamide having a molecular weight (MW) of 271 and suggested that two of these are isomers of napropa-mide having a molecular weight (MW) of 271 and the third appears to be a coupling of two molecules of napropamide having a MW of 540. Examination of the structures of the photodegradation products suggests that aqueous photolysis involves an initial rearrangement of the propanamidyl group to the 2-position or to the 4-position of the naphthaleny-

loxy (ing. Coupling at the 4-position is responsible for yielding the 540 MW product from one of the 271 MW isomers, but coupling involving the 2-position was not observed, presumably due to steric hindrance. Photodegradation of napropamide is significantly faster in water than in soil. (Doyle-PTT)

MICRORIAL DECHLORINATION OF THE HERBICIDE METOLACHLOR.

Descriptors: \*Biodegradation, \*Fate of pollutants, \*Herbicides, \*Metolachlor, \*Microbial degradation, \*Path of pollutants, Culturing technique, Degradation products, Dehalogenation, High performance liquid chromatography, Mass spectrometry, Streptomyces.

Dechlorination is an important reaction since it usually results in the detoxification of pesticides and herbicides. The ability of four microbial strains to dechlorinate metolachlor was studied in order to determine the mechanism of transformation and to isolate and identify the formed products. Strepto isolate and identify the formed products. Streptomyces sp., Phanerochaete chrysosporium, Rhizoctonia praticola, and Syncephalastrum were grown in a medium containing 0.35 mM metolachlor. A significant amount of the herbicide was dechlorinated by all cultures, resulting in the formation of seven dechlorinated products as determined by high performance liquid chromatography and mass spectrometric analyses. Transformation mechanisms included dehalogenation with subsequent hydroxylation of the chloroscetyl subsequent hydroxylation of the chloroacetyl group; further reactions led to ring formation between the acetyl group and the benzylic ethyl side chain. Dehalogenation in conjunction with demethylation at the N-alkyl substituent and hydroxmethylation at the N-alkyl substituent and hydrox-ylation at the aralkyl side chain were also ob-served. Streptomyces was the most active culture in dechlorinating metolachlor; 41% of the added herbicide was recovered as dechlorinated products after a 16 day incubation period. Dechlorinated products from P. chrysoporium, R. Praticola, and S. racemosum amounted to 28.4, 26.8, and 13.5% S. racemosum amounted to 28-4, 26.8, and 13.3% respectively, of the originally added metolachlor. Upon incubation of product metabolites G or I with Streptomyces, both compounds were further transformed, indicating metabolism of the primary products. Results suggest that metolachlor can be dechlorinated by microorganisms, but the accumulation. lation of dechlorinated products differed with species. (Doyle-PTT) W91-11377

GROUNDWATER CONTAMINATION BY ANTHROPOGENIC ORGANIC COMPOUNDS FROM WASTE DISPOSAL SITES: TRANSFOR-MATIONS AND BEHAVIOR.

Mount Royal Coll., Calgary (Alberta). Dept. of Chemical and Biological Sciences. R. Saint-Fort.

Journal of Environmental Science and Health (A) JESEDU, Vol. 26, No. 1, p 13-62, 1991. 4 fig, 13

Descriptors: \*Fate of pollutants, \*Groundwater pollution, \*Land disposal, \*Landfills, \*Organic pollutants, \*Path of pollutants, \*Waste disposal, Adsorption, Chemical wastes, Hazardous wastes, Planning, Solute transport.

Recent years have witnessed a dramatic rise in production and use of synthetic organic chemicals. It becomes apparent that modern society must either dispose of the enormous quantities of residual products (wastes) that it generates or in some way minimize or reprocess those residuals. However, in North America, as in most areas of the world, the safe disposal and management of chemi-cal wastes are becoming increasingly important as occurrences of groundwater contami

Sources Of Pollution-Group 5B

ported. After the disposal of chemical wastes in the ground, the potential for constituent(s) to leach from a disposal site, to reach the groundwater, to pressist or to be attenuated, depends on its inherent physico-chemical properties, and its resistance to removal by complex interactive physical, chemical and biological reactions in the surrounding soil-groundwater media. Effective strategies for action, contingency plans and health hazards associated with groundwater contamination in relation to water diseased acceptance to the property of the with groundwater contamination in relation to waste disposal associated problems require an integrated approach encompassing the physical and biochemical environmental interactions with the waste. Of greatest concern are anthropogenic organic contaminants which can not only be persistent and nonvolatile, but may also exhibit mobility across disposal site boundaries; a combination which may have undesirable environmental consequences. Moreover, unsegregated wastes containing a multitude of compounds represent special complex problems due to their different attenuation and chromatographic distribution characteration and chromatographic distribution characteristics at a disposal site. Descriptors: \*Bed load, \*Chromium, \*Copper, \*Godavari River, \*Heavy metals, \*India, \*Nickel, \*Path of pollutants, \*Sediment contamination, \*Sediment load, \*Suspended sediments, \*Urbanization, \*Water pollution sources, \*Zinc, Iron, Manganese, Spatial distribution, Temporal distribution

Suspended and bed sediments collected from the entire region of the Godavari River basin were analyzed for Fe, Mn, Cr, Cu, Ni and Zn. There are analyzed for Fe, Mn, Cr, Cu, Ni and Zn. There are pronounced temporal and spatial variations in the heavy metal distributions. The concentrations of heavy metals in the suspended sediments are significantly higher than the bed sediments. Throughout the basin heavy metals are enriched in the finer fractions of the bed sediments. The average heavy-metal composition of the sediments is higher when compared to the average Indian river sediments. Heavy metal concentration in the two shallow cores collected shows, to some extent, the influcores collected shows, to some extent, the influ-ence of urbanization. Compared to the other tropi-cal Indian rivers such as the Krishna, the Godavari cal indian rivers such as the Arisania, the Oodavari appears to be a significant contributor of heavy metals to the Bay of Bengal. Fluxes to the Bay of Bengal are very significant considering the enormous sediment load of the Godavari River (170 million tons per year). Except for the Pranhita, other tributaries of the Godavari do not contribute other tributaries of the Godavari do not contribute significant loads of heavy metals. All metals show high correlations among themselves and the correlation is more pronounced in suspended sediments than in the bed sediments. (Author's abstract) W91-11445

LEAD SORPTION IN CALCAREOUS SOILS. Alexandria Univ. (Egypt). Dept. of Soil and Water E. A. Elkhatib, G. M. Elshebiny, and A. M. Balba.

Environmental Pollution ENPOEK, Vol. 69, No. 4, p 269-276, 1991. 3 fig, 3 tab, 15 ref.

Descriptors: \*Calcareous soils, \*Heavy metals, \*Isotherms, \*Lead, \*Path of pollutants, \*Sorption, Adsorption, Calcium carbonate, Carbonates, Clay soils, Correlation analysis, Energy, Mathematical studies, Sandy soils, Soil types, Temperature.

Samples of three surface soils (0-30 cm) differing in Samples of three surface soils (0-30 cm) differing in location, origin, texture, and calcium carbonate content (clay, CaCO3-rich, and sandy soils, respectively), were used to study the adsorption of lead by calcareous soils at three different temperatures. The quantity of Pb sorbed by the soils followed the trend CaCO3-rich > clay > sandy. The greater amount of Pb sorbed by the CaCO3-rich soil may result from the greater quantity of calcium carbonate present. The Freundlich equation successfully described Pb sorption over an initial concentration range of 0.121-3.861 mM Pb. Freundlich K sub f values at any given temperature were centration range of 0.121-3.801 mM Pt. Freunding.

K sub f values at any given temperature were smaller for the sandy soil than for the other soils. This strongly suggests that the total sorption capacity of CaCO3-rich soils is much higher than that of the clay and sandy soils, possibly due to the formation of lead carbonate. The sorption data conformed to the Langmuir isotherm and also followed the Freundlich isotherm. For comparison, for goodness of fit in the linear form of the equ for goodness of fit in the linear form of the equa-tions, the average correlations were 0.957 for the Freundlich and 0.971 for the Langmuir isotherms. It is preferable to use the Langmuir isotherm, because the adsorption maximum can then be cal-culated. The Langmuir adsorption, K sub L, relatcunact. I ne Langmur ausorption, K sub L, relation to the energy of adsorption of Pb to the soil surface, was smallest for the clay soil, suggesting that Pb was more loosely bound and more available to plants. For all soils, the binding constant increased with temperature. (Doria-PTT) W91-11453

226-RA AND OTHER RADIONUCLIDES IN WATER, VEGETATION, AND TISSUES OF BEAVERS (CASTOR CANADENSIS) FROM AVATERSHED CONTAINING U TAILINGS

NEAR ELLIOT LAKE, CANADA.
Laurentian Univ., Sudbury (Ontario). Dept. of Biology. F. V. Clulow, M. A. Mirka, N. K. Dave, and T. P.

Environmental Pollution ENPOEK, Vol. 69, No. 4, p 277-310, 1991. 7 fig. 7 tab, 54 ref. National Sciences and Engineering Research Council of Canada Operation Grant A-5070.

Descriptors: \*Beavers, \*Bioaccumulation, \*Elliott Lake, \*Mine wastes, \*Path of pollutants, \*Radioi-sotopes, \*Radium radioisotopes, \*Tissue analysis, \*Uranium mining, Bioindicators, Canada, Correla-tion analysis, Food chains, Kidneys, Lead radioiso-topes, Liver, Muscle, Population exposure, Water analysis

Radionuclide levels were measured in tissues, gut Radionuclide levels were measured in tissues, gut contents, diet items, and water at site of capture of adult beavers from the Serpent River drainage basin, which contains uranium tailings at Elliot Lake, Ontario, and from nearby control sites. Levels of 226-Ra in beaver bone, muscle, and kidney were highest in animals from locations close to U tailings; liver levels did not vary by site. Environmental 226-Ra levels were within ranges previously reported at these or similar locations elsewhere; levels in beaver gut contents reflected levels in diet items. Concentration ratios exceeded unity only between some vegetation items and beaver bone at the Elliot Lake site and were < 0.19 between vegetation and other tissues. In two beavers with tissue levels of 226-Ra higher than others sampled, neither 232-Th nor 230-Th were detected in bone, muscle, or liver tissues. 238-U was measurable in bone, muscle, and liver; 228-Th in bone; 210-Po in bone, muscle, and liver; 228-Th in bone; 210-Po in bone, muscle, and liver; and 210-Pb only in bone. Estimated yearly intakes of radionuclides by people eating beavers were calculated to be below current allowable levels set by the Canadian regulatory authorities. The beaver is judged unsuitable as an indicator (biomonitor) of environmental radionuclide contamination, as correlation between bone and ambient (water) levels of 226-Ra is poor. RADIOACTIVITY IN WATER TREATMENT WASTES: A USEPA PERSPECTIVE.

Environmental Protection Agency, Washington, DC. Office of Drinking Water M. J. Parrotta.

Journal of the American Water Works Association JAWWA5, Vol. 83, No. 4, p 134-140, April 1991. 2 fig, 4 tab, 21 ref.

Descriptors: \*Environmental policy, \*Radioactivity, \*Water pollution sources, \*Water treatment, Administrative agencies, Aeration, Anion exchange, Cation exchange, Coagulation, Filtration, Liming, Public health, Radium radioisotopes, Radon radioisotopes, Reverse osmosis, Standards, Uranium radioisotopes.

Certain water treatment processes effectively remove naturally occurring radionuclides. Treat-ment wastes containing radiation at levels higher than background can cause disposal problems and raise public health concerns. Technologies that raise public health concerns. Technologies that appear to be effective for radionuclide removal from water include coagulation-filtration (uranium), lime softening (radium and uranium), anion exchange (uranium), cation exchange (radium), mixed-bed ion exchange (beta particles), reverse somosis (uranium, radium, and beta particles), and aeration (radon). U. S. Environmental Protection aeration (radon). U. S. Environmental Protection Agency guidance is provided in a document entitied, 'Suggested Guidelines for the Disposal of 
Drinking Water Treatment Wastes Containing 
Naturally Occurring Radionuclides.' This document should assist state agencies, water utilities, 
and others involved in the design of treatment and 
disposal operations. Where treatment exists (or is 
planned) that removes naturally occurring radionuclides from water, careful study and field and pilot 
tests for determining waste characteristics are appropriate prior to design of safe and efficient disposal operations. Treatment modifications of other posal operations. Treatment modifications of other measures should be explored to minimize water treatment wastes and to recycle, reuse, or other-wise recover wastes (or particular chemical con-stituents) to reduce the disposal problem. RADON IN HOMES FOLLOWING ITS REDUCTION IN A COMMUNITY WATER

Maine Medical Center, Portland. Dept. of Re-

P. W. Rand, E. H. Lacombe, and W. D. Perkins. Journal of the American Water Works Association JAWWA5, Vol. 83, No. 4, p 154-158, April 1991. 6 fig, 1 tab, 12 ref.

Descriptors: \*Air pollution sources, \*Path of pollutants, \*Radon, \*Water supply, Aeration, Fate of pollutants, Frozen ground, Maine, Measuring instruments, Monitoring, Radiochemical analysis, Rural areas, Snow cover, Standpipes, Steep Falls, Water analysis, Well fields, Wind velocity.

Radon in home air and domestic water supplies was measured throughout a rural community (Steep Falls, Maine) before and after the installation of a diffused aeration system that reduced water radon at the source from approximately 20,000 to <1,000 pCi/L. Analysis of hydrant water showed a gradual decline in radon with increasing distance from the well field. Data indicated two major sources of radon loss within the system: (1) serial samples from a hydrant at the base of the standpipe showed a 90% decrease of radon at certain times of the day; and (2) threemonth integrated water measurements in 21 homes showed a 40% loss from near the well fields to the Radon in home air and domestic water supplies

### **Group 5B—Sources Of Pollution**

end of the system 1 mile away. This suggests that decay time should not be overlooked when water radon levels are marginally elevated. Reducing water radon did not result in a consistent decrease in air radon in the living areas of homes as measured by three-month integrated radon track detec-tors. Expected radon differences were further modified by the characteristics of each house (e.g., air volume and the use and placement of wood stoves) and the household use of water. Further blicating radon measurement is the natural bility from year to year in wind velocity, depth of frozen ground, snow cover, and barometric pressure, as well as changes in home use. Finally, the range of error of the track-etch detectors 13, the range of error of the track-etch detectors makes demonstration of small air radon differences very difficult. Future studies should include continuous monitoring in addition to long-term track-etch detection. (Doria-PTT)

## IDENTIFICATION OF DIOXIN SOURCES IN AN INTEGRATED WOOD PROCESSING FA-

New Zealand Forest Products Ltd., Tokoroa. D. N. Campin, S. J. Buckland, D. J. Hannah, and J. A. Taucher.

Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 65-74, 1991. 10 fig, 1 tab, 11 ref.

Descriptors: \*Chlorinated hydrocarbons, \*Dioxins, \*Industrial wastes, \*Pulp and paper industry, \*Pulp wastes, \*Water pollution sources, Furans, Kraft mills, Pollutant identification, Toxic wastes, Toxicity.

A study was undertaken of the PCDD (polychlori-nated dibenzo-p-dioxin) and the related PCDF (di-benzofurans) export vectors from a major facility that comprises a bleached kraft pulp mill, paper mills, and previously, a timber processing sawmill. The PCDD and PCDF levels in pulps, untreated effluent, the final effluent, sludges, and discharge to the receiving waters were examined. The total toxic equivalents were calculated, and the individual PCDD and PCDF profiles showed that there were several contributing sources of dioxins. Despite the combination of very large flows with very low concentrations highly conservative mass balances of PCDD and PCDF translocation through a major effluent treatment system have been demonstrated. Congener profiles of PCDDs and PCDFs in benthic deposits demonstrate a high degree of similarity to the overlying water column. Discharge of PCDDs and PCDFs from the bleachperations account for 25% of the North At-Treaty Organization toxic equivalents enterlantic Treaty Organization toxic equivalents enter-ing the recipient at the time of sampling. Pentach-lorophenol may be a significant source of PCDDs and PCDFs and could account for 60% of the NATO toxic equivalents input to the recipient from the site. Measurement of congener profiles offers an effective method of identifying PCDD and PCDF sources. (See also W91-11467) (Mertz-PTT) W91-11475

### ORGANOHALOGENS OF NATURAL AND IN-DUSTRIAL ORIGIN IN LARGE RECIPIENTS OF BLEACH-PLANT EFFLUENTS.

Descriptors: \*Baltic Sea, \*Bleaching wastes, \*Chlorinated aromatic compounds, \*Chlorinated hydrocarbons, \*Path of pollutants, \*Pollutant transport, \*Vattern (lake), Lakes, Precipitation, Sweden, Water pollution, Water pollution sources.

The long-term fate of chlorophenols and adsorbable organic halogens was studied in two large recipients of bleach-plant effluents: Lake Vattern

in Sweden and the Baltic Sea. The study showed that there is a long-distance transport (>100 km) of chloroguaiacols from bleach-plants to remote parts of receiving waters. However, there was no evidence of several-year-long accumulation of chloro-organics in the water-phase. A simple water-exchange model for Lake Vattern showed that the cumulated bleach-plant discharges from the past 35 years would have increased the adsorbable organic halogens concentration in the lake by more than 100 microgram Cl/L, if no adsorbable organic halogens had been removed from the water by evaporation, sedimentation or degrada-tion. However, the observed adsorbable organic halogen concentration in Lake Vattern averaged only about 15 microgram Cl/L, which was less than the average adsorbable halogen concentration (32 microgram Cl/L) in the unpolluted tributaries of the lake. Similar investigations in the Baltic Sea showed that non-point sources, including natural halogenation processes, accounted for a substantial fraction of the adsorbable organic halogen in the open sea. The presence of 2,4,6-trichlorophenol in precipitation and unpolluted surface waters showed that non-point sources may also make a considerable contribution to the background levels of compounds normally regarded as indicators of bleach-plant effluents. Halogenated organic compounds play a dominant role in environmental pollution problems because of their persistence and bioaccumulation in organisms. A research project on long distance distri-bution of halogenated organic compounds was started in 1987 at the Swedish Environmental Research Institute. The project focused on the tran search Institute. The project focused on the transport of halogenated organic compounds, measured as adsorbable organic halogens, in Swedish rivers to surrounding sea areas. This work started in October 1987 and was finished in September 1988. Water samples were collected at 47 sampling stations in 33 drainage systems. During the same period the adsorbable organic halogen concentration in atmospheric deposition was measured at 17 sampling stations. Results showed that the annual total transport of adsorbable organic halogens to sea areas surrounding Sweden. was about 5200. sea areas surrounding Sweden, was about 5200 ton/year. Highest adsorbable organic halogen conton/year. riignest adsoroatio organic natogen con-centrations in river waters were found on the Swedish west coast (maximum 29 microgram/L) and the lowest in rivers flowing into the Bothnian Bay (maximum 29 microgram/L), in the northeast-ern part of Sweden. Analyses of adsorbable organic halogens in atmospheric deposition at sampling stations from the north to the south of Sweden, indicated that the amount of halogenated organic compounds, supplied with precipitation, was about 5100 ton/year. The mean concentration of adsorb-5100 ton/year. The mean concentration of adsorbable organic halogens in precipitation was 15 mi crogram/L. The results indicated that there were crogram/L. The results indicated that there were also sources other than anthropogenic-probably natural production of halogenated organic com-pounds. (See also W91-11467) (Mertz-PTT) W91-11506

FORMATION OF CHLOROPHENOLS AND RELATED COMPOUNDS IN NATURAL AND TECHNICAL CHLORINATION PROCESSES.

Linkoeping Univ. (Sweden). Dept. of Water and Environmental Research. F. Hodin, H. Boren, A. Grimvall, and S. Karlsson.

Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 403-410, 1991. 3 fig, 16 ref.

Descriptors: \*Bleaching wastes, \*Chlorinated hydrocarbons, \*Chlorination, \*Disinfection, \*Phenols, \*Pulp wastes, \*Water pollution sources, \*Water treatment, Bromides, Chemical reactions, Chlorinated aromatic compounds, Chlorine, Hydrogen ion concentration, Hydrogen peroxide.

The formation of chloroorganics during chlorine bleaching of pulp and chlorine disinfection of drinking water has been studied by a great number of investigators. In both cases, active chlorine of investigators. In both cases, active chlorine reacts with natural organic matter, resulting in a complex mixture of low and high molecular weight chloroorganics. Surface water was halogenated by the addition of: (1) chloroperoxidase, hydrogen peroxide and chloride; (2) hydrogen peroxide and chloride; (2) hydrogen peroxide and chloride or bromide; and (3) hypochlorite. Analysis of adsorbable organic halogen, halogenated hangels and nurseable organic compounds. genated phenols and purgeable organic compounds showed that the first two reactions produced almost the same halogenated compounds. It was also shown that active chlorine occurred as an intermediate in the reaction with chloroperoxidase, hydrogen peroxide and chloride. The hydrogen peroxide and chloride or bromide reaction implied peroxide and chloride or bromide reaction implied a marked halogenation only after the addition of bromide, and this reaction was enhanced by a low pH. Existing evidence that 2,4,6-trichlorophenol may be naturally produced was strengthened. Some evidence was also obtained indicating that enzyme-mediated reactions may contribute to the natural formation of dibenzo-p-dioxins. ## SOURCES AND EXTENT OF GROUNDWATER CONTAMINATION.

D. W. Moody.

Groundwater and Public Policy Series No. 3, May 1990. Soil and Water Conservation Society, Ankeny, Iowa. 8p, 2 fig, 5 ref.

Descriptors: \*Groundwater pollution, \*Water pollution sources, \*Groundwater quality, \*Path of pollutants, Waste disposal, Nitrates, Organic compounds, Iron, Manganese, Dissolved solids, Saline water intrusion, Agriculture, Land use.

Groundwater is an important source of drinking water for more than half of the nation's population and nearly all of its rural population. In recent years, widespread reports of bacteria, nitrate, synthetic organic chemicals and other pollutants in groundwater have increased public concern about the quality of groundwater. Groundwater contamiation can occur in many ways and from many sources, both natural and human induced. Groundwater. sources, both natural and numan induced. Oround-water commonly contains one or more naturally occurring chemicals, leached from soil or rocks by percolating water, in concentrations that exceed federal or state drinking water standards or other-wise impair its use. These include: dissolved solids and chloride; iron and manganese; and nitratenitrogen. Contaminants can enter groundwater from more than 30 different generic sources related to human activities. The most common sources of human-induced groundwater contamination can be grouped into four categories: waste disposal prac-tices (septic systems, landfills, surface impound-ments, injection wells, and land application of wastes); storage and handling of materials and

### Sources Of Pollution—Group 5B

wastes (leaking underground storage tanks, trans wastes (teaking underground storage tanks, trans-porting and stockpilling, mining practices, and oil-well brines); agricultural activities (fertilizers, pes-ticides, feedlots, and irrigation); and saline water intrusion. The organic substances most frequently reported in groundwater as resulting from waste disposal, in decreasing order of occurrence, are: trichloroethylene, benzene, tetrachloroethylene, phenolic compounds toluene, chloroform pen-plenolic compounds toluene. trichioroethylene, benzene, tetrachioroethylene, phenolic compounds, toluene, chloroform, pentachlorophenol, creosote, 1,1,1-trichloroethane, and xylene. Although little systematic information exists on the extent and severity of groundwater contamination, available evidence suggests that: (1) the shallowest aquifers generally are at greatest risk of contamination; (2) contamination of shallow aquifers by nitrates and synthetic organic chemi-cals is widespread in many areas; (3) shallow groundwater contamination can be related to land use; and (4) as yet, deeper aquifers, which commonly are used for public drinking water supplies, are relatively free from contamination. DETERMINATION OF SELENIUM SPECIES IN SPENT OIL SHALE LEACHATES BY ION CHROMATOGRAPHY.

University of Wyoming Research Corp., Laramie. Western Research Inst.

N. D. Niss, and C. R. Powers.

Available from the National Technical Information Service, Springfield, VA. 22161, as DE89-000965. Price codes: A03 in paper copy, A01 in microfiche. Report No. DOE/MC/11076-2685, September 1988. 21p, 4 fig, 2 tab, 26 ref. DOE Cooperative Agreement DE-FC21-86MC11076.

Descriptors: \*Leachates, \*Selenium, \*Oil shale, Pestriptors: "Path of pollutants, Chemical speciation, Quantita-tive analysis, Sulfur, Hydrogen ion concentration, data interpretation, Nitrates, Selenite, Selenate, Sulfates, Phosphates.

The leaching and transport of trace elements from spent oil shales is a growing area for environmental concern. Selenium is often present in spent oil shales. Under the alkaline conditions present in spent western oil shale leachates, selenium species display anionic behavior, increasing their solubility and mobility. The processes that govern the partitioning of Se species between solid and solution phases are not well understood, and computer modeling is an important tool in this area. The accuracy of geochemical model predictions depends on the thermodynamic data and mathematical formulations used in their development. To assure reliability of model predictions, it is essential assure reliability of model predictions, it is essential to validate ion speciation data obtained from geochemical models with data obtained from laboratochemical models with data obtained from laborato-ry analyses. The purpose of this study was to begin developing a method for the speciation of the two most common selenium species in spent oil shale leachate, selenite (SeO3(2-)) and selenate (SeO4(2-)), using suppressed ion chromatography. The development of a quantitative method to analyze for these anions is a prerequisite to model validation work in predicting the chemical form and mobility. work in predicting the chemical form and mobility of a Se species in spent oil shale leachates. Because of the high levels of sulfur, as well as other anions typically present in spent oil shale leachates, the typically present in spent oil shale leachates, the development of a separation scheme for SeO3(2-) and SeO4(2-) must also minimize these expected interferences. Development of a Se speciation method first used a high capacity anion exchange column with the standard anion eluent (1 mM CO3/0.9 mM HCO3). This approach to the separation of SeO3(2-) and SeO3(2-) was not acceptable due to interferences from nitrate, sulfate, and phosphate. The next approach used the same column with a 1-mM carbonate eluent, adjusted to pH 12 with 10 M sodium hydroxide. The elevated pH of the eluent eliminated interference problems with the sulfate and phosphate ions, but problems developed in producing repeatable retention time and peak area data for SeO3(2-) and SeO4(2-). Repeatability problems were attributed to several factors peak area data for SeU3(2) and SeU3(2) and Seu3(2) bility problems were attributed to several factors including eluent strength, pH, eluent flow rate, and adsorption sites on the stationary phase. Although sediments generally are considered to provide beneficial effects in terms of water quality movement through the 'sorption' of pollutants from the water column, contaminated sediments also may result in adverse effects. The interactions of both metals and organic contaminants with suspended and bed sediments significantly affect the transport and transformation of these pollutants in streams and lakes. Information about these interactions is important in sessengia heavarie of collutants. streams and takes. Information about these interac-tions is important in assessing hazards of pollutants exposure in freshwater systems. Research into the fate and transport of sediment-associated contaminants is reviewed. An overview of contaminant modeling is provided along with model descrip-tions of chemical and biological transformation processes, and research on the physical movement of contaminated sediment, including near bed sedi-ment transport and advective-dispersive transport ment transport and advective-dispersive transport in the water column. Adsorption-desorption is the most dominant of the many processes that are important in assessing the hazards associated with contaminated sediments. Additional research is needed to formulate mechanistic models that accurately reflect the adsorption-desorption process for rately reflect the adsorption-desorption process for both metals and organics in natural systems con-taining a mixture of sediment types. PRELIMINARY DATA SUMMARY FOR THE MACHINERY MANUFACTURING AND RE-BUILDING INDUSTRY.

BUILDING INDUSTRY.
Environmental Protection Agency, Washington, DC. Office of Water Regulations and Standards. Available from the National Technical Information Service, Springfield, VA. 22161, as PB90-126525. Price codes: A17 in paper copy, A01 in microfiche. Report No. EPA 440/1-89/106, October 1989, 381p, 5 fig, 71 tab. EPA Contract Nos. 68-03-3411, 68-03-3548, and 63-03-3339.

Descriptors: \*Data collections, \*Economic aspects, \*Industrial wastewater, \*Water pollution control, \*Water pollution sources, Costs, Environmental protection, Organic compounds.

The US EPA has conducted a preliminary study of machinery manufacturing, rebuilding, and maintenance facilities because of concern for the potential discharge of toxic and hazardous pollutants and in response to findings and recommendations made in discharge of toxic and hazardous pollutants and in response to findings and recommendations made in the Domestic Sewage Study. The purpose of the machinery manufacturing and rebuilding (MM and R) project was to prepare a preliminary data summary to assist the Agency in deciding whether to develop national effluent limitations guidelines and standards for MM and R facilities. This preliminary data summary includes two studies: a technical support study and an exponentic impact and cal support study and an economic impact and cost-effectiveness study. The results of the prelimi-nary analyses indicate that discharges of pollutants MM and R facilities are environmentally significant and that developing a regulation to con-trol these discharges is appropriate. MM and R facilities generate raw wastewater containing 150 million lbs/yr of toxic metals, 36.3 million lbs/yr of toxic organics, and 7,500 million lbs/yr of conven-tional pollutants. The total wastewater flow esti-

mated for MM and R facilities is 2.4 trillion L The MM and R raw wastewater flow and pollut-ant loading estimates are based on data represent-ing about 278,000 facilities with more than nine ing about 275,000 facilities with more than lime employees. The cost-effectiveness analysis estimated the annualized cost/pound of pollutant removed and per pound-equivalent of pollutant removed for the one control option considered by the technical analysis. Based on the cost per pound-equivalent removed, the control option considered is most cost-effective for the Office Machine Manufacturing (\$19 and \$46 per pound-equivalent removed for direct and indirect dischargers) and Aircraft redirect and indirect dischargers) and Aircraft re-building (\$28 and \$126 per pound-equivalent re-moved for directs and indirects) segments. It is least cost-effective for Bus and Truck Rebuilding (\$39,486 and \$43,444 per pound-equivalent re-moved for direct and indirect dischargers) and Bus and Truck Maintenance (\$3,627 and \$8,077 for directs and indirects). Cost per pound-equivalent removed for the remaining segments range from \$125 to \$1,791 for direct dischargers and from \$158 to \$8,061 for indirect dischargers. (Lantz-PTT) W91-11589 W91-11589

TRENDS IN WATER-QUALITY DATA IN

Geological Survey, Austin, TX. Water Resources T. L. Schertz.

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 89-4178, 1990. 177p, 25 fig, 8 tab, 18 ref, 2 plates.

Descriptors: "Hydrologic data collections, "Moni-toring, "Texas, "Water quality, "Water quality trends, Alkalinity, Brazos River Basin, Colorado River Basin, Dissolved oxygen, Guadalupe River Basin, Hydrogen ion concentration, Nutrients, Pes-ticides, Red River Basin, Rio Grande Basin, San Antonio River Basin, Sulfates, Trinity River Basin, Water pollution sources.

Data for approximately 40 water quality constituents from 117 stations in Texas were statistically analyzed for detectable trends for the 1975-86 water years. Data for approximately 35 water quality constituents from 98 stations were analyzed for detectable trends for the 1969-86 water years. The methods used were modified from those previously developed for a national trend study. The detectable trends of most inorganic constituents showed predominantly decreasing concentrations for both the 1975-86 and 1969-86 water years, although several regional trend patterns are evident. Areas of decreasing concentrations in the lower and coastal plains of Texas and increasing concentrations in the upper reaches of the Red, Brazos, and tions in the upper reaches of the Red, prazos, and Colorado River basins are evident in both time-frames for almost all of the dissolved ions, total hardness, and specific conductance. An area of increasing concentrations in the Rio Grande basin is evident for the same constituents for 1975-86, but a lack of data prior to 1974 prevented trend analysis for 1969-86. Increases in sulfate concentrations in the active coartel segment of the State partitled. sis for 1969-86. Increases in sulfate concentrations in the eastern coastal region of the State persisted for both time-frames, unlike trends in the region for the other dissolved ions. Paper mills, coal-fired, and lignite-fired power plants, and petrochemical plants common to this area may be the source of increased sulfate in the rivers. The trend patterns in nutrients and dissolved oxygen indicate improvement in the water quality in the upper Trinity River basin, possibly resulting from improvement in municipal wastewater treatment in the Dallas-Fort Worth area. Trend patterns in these constituents also indicate degradation in the water Dallas-Fort constituents also indicate degradation in the water quality of the San Antonio and Guadalupe Rivers quality of the San Antonio and Guadalupe Rivers that may be due to municipal waste from the city of San Antonio. The trends in both areas are evident in the 1975-86 and 1969-86 timeframes. Trends in pH were almost all increasing for both periods whereas trends in alkalinity were predominantly decreasing for both periods for the entire State. The cause of the widespread and opposite trends detected in these constituents is uncertain. Concentrations of trace elements and pesticide constituents were generally small and often less than the analytical detection limit. Few trends were detected for any of the constituents and none

ASSESSMENT OF AGRICULTURAL NUTRI-ENT POINT SOURCE DISCHARGE FROM TILE DRAINS, SPRING AND OVERLAND RUNOFF FROM TWO FARMS, DAUPHIN COUNTY, PENNSYLVANIA. Susquehanna River Basin Commission, Harrisburg, PA. Resource Quality Management and Protection Div.

S. Takita, A. N. Ott, J. D. Graham, and J. J.

Hauenstein. Susquehanna River Basin Commission, Harrisburg, Pennsylvania. Publication No. 135, March 1991. 95p, 16 fig, 20 tab, 3 ref, append. EPA Grant No. 1-003992-90-0.

Descriptors: \*Agricultural runoff, \*Nutrients, \*Pennsylvania, \*Tile drains, \*Water pollution sources, Agriculture, Case studies, Conestoga River Basin, Fertilizers, Land use, Nitrogen, Phos-phorus, Pollutant load, Precipitation, Surface runoff, Susquehanna River Basin.

The Halifax farm field drain and spring are located below the water table for most of the year and are, therefore, believed to be collection points for the very shallow groundwater. This situation provides very shallow groundwater. This situation provides a relatively enclosed shallow flow system which allows the calculation of a reasonable nutrient budget. The measured runoff ranged from 16% to 51% of the annual precipitation. The annual N and P loss to the combined water outflow of a tile drain, spring, and overland runoff from the 10.19 acre Halifax farmed drainage area ranged from 23 to 119 lbs/acre of N and 0.21 to 0.56 lb/acre P. The Enterline farm field drain is located at a depth which is above the water table most of the time and, therefore, only flows during and immediately following precipitation events. Unlike the Halifax flow system, this flow system ranged only from 5% to 11% of the annual precipitation, and does not warrant a nutrient budget. The nutrient loss to the water outflow of the measured Enterline flow system ranged from 4 to 10 lbs/acre N and 0.06 to the water outflow of the measured Enterline flow system ranged from 4 to 10 lbs/acre N and 0.06 to 0.11 lbs/acre P. Since slightly more than half of the drainage area is farmed and most of the remain der wooded, the yield per acre farmed is 8 to 20 lbs/acre N and 0.11 to 0.22 lbs/acre P. The 4 to 10 lbs/acre N and 0.11 to 0.22 lbs/acre P. The 4 to 10 lbs/acre N loss at Enterline is similar to the average annual N losses estimated for farmed Susquehanna River sub-basins that are at least 50% forested. The intensely farmed Conestoga River basin averages 33 lbs/acre N loss and a 2.44 lbs/acre P loss. The Halifax farm, which does not have non-ferm diluterage of farm dilution runoff, appears in the high N range, but neither farm remotely approaches the P loss found in the Conestoga or other highly farmed basins. ### 5C. Effects Of Pollution

FEATURES OF THE LIMNOLOGICAL BE-HAVIOR OF SALTO GRANDE'S RESERVOIR (ARGENTINA-URUGUAY).

DECISION S.R.L., Buenos Aires (Argentina). L. E. Beron.

Ecological Modelling ECMODT, Vol. 52, No. 1/2, p 87-102, November 1990. 7 fig, 2 tab, 13 ref.

Descriptors: \*Argentina, \*Eutrophication, \*Lim-nology, \*Reservoirs, \*Water pollution effects, Algal growth, Cyanophyta, Ecology, Lake ecolo-gy, Microcystis, Nutrients, Physical parameters, Phytoplankton, Residence time, Secchi depth, Tur-bidity, Turbulence.

Salto Grande's reservoir (Argentina) is a river-like reservoir of 780 sq km with multiple arms. The

limnological behavior of the impoundment shows that excessive fertilization (eutrophication) in the lower half of the reservoir is of sufficient magnitude to cause impairment of recreational areas. The reservoir presents different subenvironments: several differentiated arms plus a main channel. Under normal or elevated-flow conditions, water travel time is such that less than the maximum possible time is such that less than the maximum possible number of algae develop near the dam, compared to the norm in other lakes and reservoirs. These conditions increase the time for algae development in the reservoir, and more importantly, allow for the sedimentation of inorganic turbidity, which under most conditions limits available light reducing algal group helpow, what normally occurs in a steal crowth below, what normally occurs in under most condutors limits available inja reduc-ing algal growth below what normally occurs in water bodies. At the same time some physical factors operate with unequal intensity in both sys-tems. In the lateral arms lentic conditions prevail, whereas in the main channel the intensity of the turbulence and the horizontal transport establish lotic conditions. The nutrient conditions of the lotic conditions. The nutrient conditions of the water characterize the reservoir as mesotrophic, and occasionally eutrophic. Dissolved oxygen constitution is acceptable in the lake. The relationship between Secchi depth and the hydraulic residence time clearly shows that, when the water is slow, turbidity decreases, thus more algal growth takes place. The reservoir may be considered as a system composed of two markedly different sub-systems regarding their biological manifestations: systems regarding their biological manifestations: the system of lateral arms where the phytoplank-ton is exclusively dominated by Cyanophyta, particularly Microcystis species, and the main channel characterized by diatomous algae, with absolute dominance of Melosira species. The evolution of algae concentrations, and of some physico-chemical parameters, emphasize the unequal behavior of both subsystems, implying the development and persistence of different environmental conditions. Results indicate that the phytoplankton of the reservoir is limited by the inorganic turbidity, except at the indicate that the phytoplankton of the reservoir is limited by the inorganic turbidity, except at the end of the arms, and is mainly determined by water renewal in the center of the reservoir and by the washing effect due to rainfall on the lateral arms. NEW DEAD SEA. G. L. Gist.

Journal of Environmental Health JEVHAH, p 20-22, Spring 1991. 1 fig, 1 tab.

Descriptors: \*Environmental effects, \*Oil pollution, \*Oil spills, \*Path of pollutants, \*Persian Gulf, \*Water pollution effects, Aquatic plants, Benthos, Cleanup operations, Corals, Crabs, Mangrove swamps, Mollusks, Oysters, Water pollution.

On Jan. 25, 1991, a new type of terrorism was introduced to the world. Iraqi troops released oil into the Persian Gulf from the Sea Island superand the Persian Guil from the Sea Island super-tanker loading facility and from five scuttled tank-ers located 10 miles off the coast of Kuwait. The Persian Gulf is a shallow marginal sea of the Indian Ocean. The Gulf varies in width from 35 miles at the Strait of Hormuz to 210 miles near the center. The sea floor is shallow, rarely exceeding 300 feet in depth. The effects of crude oil in open sea are seen for approximately three years after release. Since the Sea Island release was inland, the effects will be felt for a much longer time. Bottom dwellers, such as crabs, oysters and mollusks will be killed, as will the sea grass beds and algal flats, which provide food for countless other marine organisms. Several rare or endangered species of flora and fauna are threatened. Mangrove stands will be significantly affected and coral reefs will die back to at least 10 feet below the Gulf's sur-face. Populations of bottlenose dolphins, whales, hawksbill and green turtles, and caspian terns will be reduced to an unknown degree by exposure to be reduced to an unknown degree by exposure to the oil. Perhaps the most threatened species is the dugong. Cleanup will be complicated by the fact that the slick is located in a war zone. Early response has been impossible. The slick was ignited during the early part of the disaster. Burning is an effective technique against freshly spilled oil. The ocean, however, serves as a heat sink making it difficult to maintain a sustained burn. The cost of cleanup has been estimated at \$5 billion. (Mertz-PTT)

EFFECTS OF POLLUTION ON HETEROZY-GOSITY IN THE BARNACLE BALANUS AM-PHITRITE (CIRRIPEDIA: THORACICA), Padua Univ. (Italy). Dept. of Biology.

T. Patarnello, R. Guinez, and B. Battaglia.

Marine Ecology Progress Series MESEDT, Vol.

70, No. 3, p 237-243, March 12, 1991. 2 fig, 6 tab,

35 ref.

Descriptors: \*Barnacles, \*Crustaceans, \*Genetics, \*Italy, \*Thermal pollution, \*Water pollution effects, Chemical wastes, Electric powerplants, Heavy metals, Lagoons, Water pollution.

The effects of thermal and chemical pollution on gene and genotype frequencies and on multilocus structure were studied in 3 populations of the barnacle Balanus amphitrite Darwin from the lagoon of Venice, Italy. One of these populations (oppulation A) was subjected to high chemical pollution; the second (population B) was constantly exposed to temperatures about 10 C higher than the rest of the lagoon since it was settled in front of an electric power plant outflow; and the third (population C) was sampled in an unpolluted area of the lagoon as a control. Juvenile and adult age classes of each of the 3 samples were studied by electrophoretic analysis of the polymorphic loci Mpi, Pgi, and Pgm. Significant differences were found between Population A adults and both B and C adults for the majority of the genetic comparisons. B and C adult populations did not differ significantly. Statistical comparisons among the three juvenile populations showed a high genetic homogeneity. Comparisons between the two age classes within each of the three populations exhibited significant differences only between adults and juveniles of Population A at the level of gene and genotype frequencies. Moreover, in Population As a significant differences only between adults and juveniles of Population A aut the level of gene and genotype frequencies. Moreover, in Population As a significant differences only between adults and juveniles of B and C The effects of thermal and chemical pollution on zygote class was observed. No differences were detected between adults and juveniles of B and C samples. These results suggest the action, in Population A, of some selective factor during the postsettlement period. Thermal pollution does not seem to play any important selective role. The hypothesis is advanced that selection is determined by heavy metals. (Author's abstract) W91-10518

MEIOFAUNA OF AN EXPERIMENTAL SOFT BOTTOM ECOSYSTEM--EFFECTS OF MA-CROFAUNA AND CADMIUM EXPOSURE.

Stockholm Univ. (Sweden). Dept. of Zoology. B. Sundelin, and R. Elmgren.

Marine Ecology Progress Series MESEDT, Vol. 70, No. 3, p 245-255, March 12, 1991. 3 fig, 2 tab,

Descriptors: \*Benthic fauna, \*Bioassay, \*Cadmi-um, \*Macroinvertebrates, \*Sediment contamina-tion, \*Toxicity, \*Water pollution effects, Amphi-pods, Biomass, Ecological effects, Heavy metals, Nematodes, Seed-shrimp, Toxicology, Water pol-lution.

The effects of macrofauna (the amphipod Pontoporeia affinis) and of exposure to cadmium at 0 (control) and about 5, 50 and 150 microgram/L on a meiofauna population were studied in small, flow-through laboratory microcosms. Meiofauna was derived from a soft sediment benthos commuwas derived from a soft sediment benthos commu-nity, typical below the thermocline in the northern Baltic proper (salinity 6 to 8 parts per thousand). In a first experiment (265 days) subadult amphi-pods were added, while in a second experiment (450 days) both juveniles and subadults were in-cluded. After 265 days at natural field amphipod densities total meiofauna abundance was lower than in control experiments without amphipods. In contrast, non-nematode meiofauna, in particular Turbellaria and harpacticoids, increased in the presence of amphipods. Effects of cadmium expo-sure on the meiofauna could thus be due either to direct toxicity, or to changes in macrofaunal abundance or activity caused by cadmium. Sediment cadmium concentration was a highly significant function of cadmium concentration in the input

Effects Of Pollution-Group 5C

water. Significant negative dose-response relationships were obtained in the second experiment (460 days, with amphipods) for total meiofauna abundance and biomass, non-nematode biomass, nematode abundance, ostracod abundance and turbellarian abundance. Overall, ostracods were found particularly sensitive to cadmium exposure, while Turbellaria and monothalamous Foraminifera sometimes increased in cadmium-dosed microcosms, presumably due to reduced competition or predation. The microcosm system tested was found predation. The microcosm system tested was found suitable for long-term experiments, and could maintain a near-natural density of meiofauna and P. affinis for over one year. Such long-term experiments demonstrated effects of cadmium even at a concentration as low as 6 microgram/L, in the presence of sediment. (Author's abstract) W91-10519

FIELD SURVEY AND HYDRAULIC STUDY OF 'AOSHIO' IN TOKYO BAY.
National Inst. for Environmental Studies, Tsukuba

National History (Japan). K. Otsubo, A. Harashima, T. Miyazaki, Y. Yasuoka, and K. Muraoka. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 51-55, 1991. 6 fig, 2 tab, 5 ref.

Descriptors: \*Aoshio phenomenon, \*Eutrophication, \*Hydrogen sulfide, \*Japan, \*Marine pollution, \*Tokyo Bay, \*Upwelling, \*Water pollution effects, Anoxic conditions, Model studies, Remote sensing, Wind effects.

The color of the sea surface changes to milky-blue and many fish and shellfish are killed when the 'blue tide', or 'aoshio' phenomenon occurs. Aoshio 'blue tide', or 'aoshio' phenomenon occurs. Aoshio has appeared only in the summer and only in a particular eutrophic coastal area of Tokyo Bay in Japan. Field surveys at the sea surface by ship and from the air via helicopter assessed the aoshio phenomenon physicochemically and biologically. Aoshio is believed to be caused by a hydrogen-sulfide-containing anoxic bottom-water mass which develops off the coast in the summer. This water upwells in the coastal area when offshore winds blow for several days in a row. Before reaching the surface, the dissolved hydrogen sulfide is oxidized to colloidal sulfur particles. The fide is oxidized to colloidal sulfur particles. The milky-blue color is attributed to the random reflection of sunlight off these particles. Numerical simution of suming to it trees particles. Numerical simulations using two-dimensional equations for stratified flow were used to explain the water-mass ascent. (Brunone-PTT) W91-10529

IMPACT OF NUTRIENT ENRICHMENT AND THEIR RELATION TO THE ALGAL BLOOM IN THE ADRIATIC SEA.

Institute of Oceanography and Fisheries, Split

institute of Oceanography and Fisheries, Spitt (Yugoslavia). I. Vukadin. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 145-148, 1991. 4 tab, 8 ref.

Descriptors: \*Adriatic Sea, \*Algal blooms, \*Enrichment, \*Eutrophication, \*Nutrient concentrations, \*Path of pollutants, \*Water pollution effects, Estuaries, Industrial wastes, Municipal wastes, Runoff, Stratification.

Extraordinary manifestations of eutrophication in the Adriatic Sea during the last few years have been due to the combined effects of different physbeen due to the combined effects of different phys-icochemical and meteorological factors. Perma-nent inputs of nutrients, particularly in the north-ern Adriatic via river runoffs and municipal sewage during calm summers, cause marked strati-fication of the water column and reduction of horizontal advection. These two effects provide the ideal conditions for a single species bloom.

Calculation of the nutrient balance provides a better explanation of algal blooms in the Adriatic, better explanation of algal blooms in the Adriatic, showing that the source of nutrient input is the northern Adriatic in front of the Po River estuary and the estuaries of other northern Italian rivers. These river runoffs and industrial wastes are the source and direct cause of eutrophication and algal lacense while metacorological and hydrological blooms, while meteorological and hydrological conditions support the spreading and persistence of the bloom in the northern and middle Adriatic. CHANGES AND STRESS SIGNS IN PLANK-TON COMMUNITIES AS A RESULT OF MAN-INDUCED PERTURBATIONS IN ENCLOSED BALTIC).

secnnion - Israel Inst. of Tech., Haifa. Faculty of Agricultural Engineering. B. Kimor. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 171-174, 1991.

Descriptors: \*Baltic Sea, \*Coastal waters, \*Eutrophication, \*Marine pollution, \*Mediterranean Sea, \*Plankton, \*Species composition, \*Water pollution effects, Algal blooms, Dam effects, Enrichment, Fishkill.

Eutrophication induced by nutrient enrichment in coastal waters stimulates development of phyto-plankton blooms with frequently deleterious effects to marine life. A number of case histories are found in the land-locked Mediterranean and Baltic Seas. Among them is the recent occurrence of the potentially toxic dinoflagellate Prorocentrum minimum in the Adriatic and Kiel Fjord and of the prymnesiomonad Chrysochromulina polylepis associated with fish kills in the Baltic. Other changes affecting the periodicity of the algal blooms with drastic effects on coastal fisheries have been reported from the Levant Basin following the activation of the Aswan High Dam on the Nile. An extensive before and after monitoring program is proposed for particularly vulnerable areas aimed at the denot particularly vulnerable areas aimed at the de-tection of stress signs manifested by subtle or abrupt changes in species composition and a down-shift in the size of phytoplankton components. Implementation of modern field and laboratory technologies, along with a better understanding of organismic biology can be used to complement one another for an effective monitoring program in the coastal waters of coastal seas. Relationships among high Secchi disk visibility values, dissolved oxygen deficits in bottom water layers, and a bloom of the giant diatom Coscinodislayers, and a forth of the giant thatom cost mous-cus wallesii were investigated in eastern Seto Inland Sea (SIS), Japan. C. wailesii first appeared in autumn when water temperatures went down, utilizing high levels of nutrients to build its popula-tion density. Decline of the algal bloom created a applied position of algal remains onto the bottom mud. Consequently, Secchi disk visibility increased in the area and the phytoplankton cells continued to decompose in the sediment. During the winter, with low water temperatures the organic matter remained in the sediment, while with higher water temperatures the organic matter broke down. The cause of the recent dissolved oxygen deficit of the bottom water in SIS was the decomposition of the giant diatom population in the sediment, accelerated by the increased bottom water temperature. In the past two decades, a fish farming industry using net cages has developed in the coastal waters throughout Japan. Such fish farming has allowed the production of large amounts of valuable fish and their supply to the markets in major cities on a regular basis. However, fish farming is often accompanied by serious organic pollution of the water and increased bottom sediment in the vicinity of the cages, since approximately 90% of the food for the fish results in organic discharge to the environment around the fish farm. Organic pollution of soft bottom sediment is often accompanied environment around the instram. Organic politi-tion of soft bottom sediment is often accompanied by the development of reducing conditions in the sediment and deoxidation of the bottom water, as a result of the decomposition of abundant organic matter. The benthic communities in organically polluted areas are subject to catastrophic environ-mental disturbances. Results of surveys in Tomoe Cove, Kyushu, Japan show dramatic changes in fauna and reduction in abundance of members of Tauna and reduction in abundance of members of the benthic communities as a result of organic pollution accompanying fish farming. Dominant species tend to be those with short life cycles and high potential for population growth, to quickly colonize these polluted areas. (Author's abstract)

Based upon the Andersen and Ursin ecological model, an adequate model was constructed to evaluate quantitatively the overall impact of industrial large-scale development on fisheries at Osaka Bay. The model treats quantities of phosphorus as index of biomass of each species as well as mass of inorganic matter, converted by phosphorus equiva-lent. The model must consist of simultaneous differential equations to describe the ecosystem, be-

### Group 5C-Effects Of Pollution

cause of the high number of physical and biological components of the system. Twenty-three species, selected from more than eighty species of commercial fish, were used in the analysis. The patterns of changes in biomass of dominant species, which is caused by eutrophication, can be explained by the model. Verification of the model was accomplished by comparing the calculated was accomplished by comparing the calculated panied by the model. Verification of the model was accomplished by comparing the calculated results with the actual changes of catch and body weight over time. The simulated results for two years, 1956 to 1957, are, on average, comparable to the actual variations, However, the results for several species, including sea bass, flat fish, crab, mantis shrimp, and cuttlefish, differ significantly from observed data, attributed to the lack of accurate parameters of anabolism and catabolism for younger-aged stages of these species. SIMULATION OF BIOECOLOGICAL AND WATER QUALITY PROCESSES IN EN-CLOSED COASTAL SEAS. Halcrow (William) and Partners, Swindon (Eng-

Jang, D. E. Reeve, C. R. Hoggart, and S. R. Brown. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 259-263, 1991. 3 fig, 11 ref.

Descriptors: \*Algal growth, \*Coasts, \*Eutrophica-tion, \*Marine pollution, \*Mathematical models, \*Model studies, \*Path of pollutants, \*Water pollu-tion effects, \*Water quality, Anoxic conditions, Computer programs, Hydrodynamics, Microorganentation, Solute transport

In enclosed marine waters, eutrophication often leads to prolific growth of algae, an accumulation of sediments, and the onset of anaerobic conditions of sediments, and the onset of anaerobic conditions following the death and decay of plant species. A restoration program may have to run over many years, so that any mathematical model capable of providing reliable long-term predictions must run in a fraction of real time. On the other hand, short term water quality changes are also of interest, such as the decay of bacteria discharged from a such as the decay of bacteria discharged from a sewage outfall. Environmental management can be split into the following categories: short-term phe-nomena, such as algal blooms and accidentar leases of toxic chemicals; longer-term phenomena, lasting several years; and combinations of the two fundamental components: a hydrodynamic/solute rangamental components: a hydrodynamic/solute transport model, and an ecological process model. Both models have been installed on personal com-puters. The ecological process model can produce a one year prediction in approximately seven min-utes per box. Both models have been validated against extensive experimental data sets, and have been used in coastal management projects. (Brun-

STUDIES ON THE SITUATION OF POLLU-TION AND COUNTERMEASURES OF CON-TROL OF THE OCEANIC ENVIRONMENT IN ZHOUSHAN FISHING GROUND: THE LARG-EST FISHING GROUND IN CHINA. nental Sciences.

of Environ

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 281-288, 1991. 4 fig, 2 tab, 2 ref.

Descriptors: \*China, \*Coastal waters, \*Fisheries, \*Marine pollution, \*Wastewater pollution, \*Water pollution effects, \*Water pollution sources, \*Yangtze River, Bioaccumulation, Caoe River, Fish migration, Hangzhou Bay, Qiantang River, Species diversity, Toxicity, Trace metals, Yong River.

Zhoushan fishing grounds are located in the east-ern part of Hangzhou Bay, China, close to the

shoreline of Zhejiang Province and the Shanghai Municipality and encompassing areas of the Yangtze River, Qiantang River, Yong River, and Caoe River. The continental coastline is 1500 km in length, with a total area of fishing of about in length, with a total area of fishing of about 100,000 sq km, and is a spawning ground for various fish, shrimp, and crabs. The most abundant species are hairtail, larger yellow croaker, little yellow croaker, and cuttlefish. The annual catch is yellow croaker, and cuttlenist. In eannual catch is about 800 thousand tons, one-third of the national total. Lately, however, the annual catch has been reduced, dropping to 50% of former levels. Besides overfishing, the oceanic environment has become increasingly polluted. With the most developed coastline in China, wastewater discharge into the fishing grounds is as high as two billion. into the rishing grounds is as fight as two billion tons, causing serious organic pollution and levels of trace metals (Cu, Zn, Pb, and Cr) violating environmental standards. This pollution directly affects the structure and stability of oceanic ecosystems, changing migration routes of fishes and continuous from examinar properties. emigration from spawning grounds, and continual-ly increasing levels of residual toxins in aquatic products. These problems have been brought to the attention of the Chinese government, and measures are under way to improve the oceanic environmental quality. (Author's abstract) W91-10559

INCIDENCE AND ECOLOGY OF MARINE FOULING ORGANISMS IN THE EASTERN HARBOUR OF ALEXANDRIA, EGYPT.
Institute of Oceanography and Fisheries, Alexan-

dria (Egypt). M. M. El-Komi.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 289-296, 1991. 2 fig, 3 tab, 10 ref.

Descriptors: \*Alexandria, \*Biofouling, \*Coastal waters, \*Egypt, \*Marine pollution, \*Wastewater pollution, \*Wastewater pollution, effects, Abundance, Algae, Alkalinity, Amphipods, Ascidians, Barnacles, Bryozoans, Dissolved oxygen, Fouling, Hydroids, Juvenile growth stage, Polychaetes, Seasonal variation, Seawater, Species diversity, Sponges, Water temperature

The Eastern Harbour of Alexandria is a relatively small semi-circular polluted bay, covering an area of about 2.8 sq km. The seasonal changes, intensity and components of fouling on exposed test panels and components of routing on exposed test panels for short-term and long-term intervals were investigated in relation to prevailing environmental conditions in the Eastern Harbor from March 1984 to March 1984. The intensity of fouling on exposed test panels for long durations is considerably more dense than total fouling biomass on exposed panels with short-term exposure during the same period. The fouling colonies on the submerged panels reached a saturation point after three to six months. During the period of investigation, a total of 41 species of sedentary marine fouling organisms were noted. These species mainly belonged to eight main fouling groups: barnacles, serpulid tube worms, ascidians, bryozoans, amphipods, hydroids, algae, and sponges. The inflow of 36,000 cu m/day of untreated sewage into the harbor shows seasonal of ultracted swage into the nation's single seasonal fluctuations in the environmental conditions, particularly the dissolved oxygen, oxidizable oxygen, and alkalinity of seawater. The presence of fouling larval stages in plankton samples throughout most of the year did not demonstrate the actual settleof the year did not demonstrate the actual settlement intensity of fouling organisms, but the settling plate experiments did. Water temperatures affected the distribution of marine organisms and their abundance. (Brunone-PTT) W91-10560

WATERBORNE DISEASE OUTBREAK.

National Bacteriological Lab., Stockholm Y. Andersson.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 13-15, 1991. 2 fig.

Descriptors: \*Disinfection, \*Drinking water, \*Epi-Descriptors: "Disintection, "Drinking water, "Epidemiology, "Human diseases, "Sweden, "Water pollution sources, "Water quality monitoring, "Water treatment, Chlorination, Contamination, Fecal bacteria, Hydrogen ion concentration, Legislation, Public health, Water pollution effects.

Between 1980 and 1989, 63 waterborne disease outbreaks were reported in Sweden, with a total of 32,250 known cases. These outbreaks range from small household incidents to community outbreaks with thousands of victims. The largest outbreak occurred in 1988 in Boden, a city in the very north of Sweden with 26,000 inhabitants and a military camp with about 1,000 soldiers at risk. Beginning March 24, an estimated total of 10,700 (41%) of the march 24, an estimated total of 10,000 (41%) of the inhabitants and 341 (34%) of the soldiers fell ill with gastrointestinal symptoms. Investigations revealed that the tap water was bacteriologically similar to untreated raw water, showing moderate degrees of fecal contamination. It was disclosed that during the installation on March 22 of an electronic control extens for water treatment, the electronic control system for water treatment, the water treatment plant's chlorination and monitoring systems were out of order, and that rapid sand filtration had been the only water treatment. The shape of the epidemic curve resembled that of a common source outbreak. The duration of sympcommon source outbreak. The duration of symptoms ranged from less than one day to more than 20 days. Most people were ill one to three days. A new (January 1990) drinking water act provides stricter controls over microbiological and chemical sampling of raw and tap water and the monitoring of pH and chlorination. In February 1989, an outbreak of waterborne cryptosporidiosis associated with contaminated surface water in the upper Thames catchment was identified. Less than 0.01% of the population suffered symptoms sufficient for them to seek medical advice. Nevertheless, the impact of the outbreak on the community and the water undertakers was considerable, and an expert committee was appointed to advise on research and measures to control the disease and prevent future waterborne outbreaks. One of the committee's interim recommendations was to gather information on the occurrence of cryptosporidium oocysts in the aquatic environment, particularly sources used for abstrac-tion and production of drinking water. The origin of the contamination incidents recorded at Far-moor reservoir and the River Tillingbourne are still unclear. However, in the latter case agriculturall input is strongly suspected because the river receives no sewage effluent. Much of the area adjacent to the river is used as pasture for cattle. adjacent to the river is used as pasture for cattle. During the outbreak investigation in Swindon and Oxford, there was epidemiological evidence of the involvement of a tributary of the River Thames, which also receives minimal sewage effluent. ATRAZINE HAZARDS TO FISH, WILDLIFE, AND INVERTEBRATES: A SYNOPTIC REVIEW.

Patuxent Wildlife Research Center, Laurel, MD.

Available from the National Technical Information Service, Springfield, VA. 22161, as PB89-204671. Price codes: A04 in paper copy, A01 in microfiche. Biological Report 85(1.18), Contaminant Hazard Reviews Report No. 18, May 1989. 53p, 7 tab, 119

Descriptors: \*Atrazine, \*Fish, \*Herbicides, \*Invertebrates, \*Literature review, \*Path of pollutants, \*Water pollution effects, \*Wildlife, Agriculture, Bioaccumulation, Birds, Ecological effects, Ecotoxicology, Mammals, Organic compounds, Toxicity

The herbicide atrazine is the most heavily used agricultural pesticide in North America. Domestically, more than 50 million kg are applied yearly to more than 25 million ha, primarily to control weeds in corn and sorghum crops. Atrazine residues have been detected in runoff from treated fields in lakes and streams at phytotoxic levels. Birds and mammals were comparatively resistant, with a low probability for atrazine accumulation and retention. Data are lacking on indirect effects of atrazine on wildlife granivores and insectivores. Direct effects to aquatic fauna occur at 94 microgm/L, and higher; however, indirect effects may occur at 20 microgm/L, and higher, partly through reduction of the food supply of herbivores, and partly through loss of macrophyte habitat. Bioaccumulation of atrazine is limited, and food chain biomagnification is negligible in aquatic ecosystems. Birds are comparatively resistant too atrazine, having a low probability for uptake and retention. Known acute oral LD-50 values for birds are > 2,000 mg/kg body weight, and dietary LD-50s are > 5,000 mg/kg ration. However, indirect ecosystem effects of atrazine on seed-, and insect-eating birds are unknown, and should be investigated. Data are lacking for atrazine toxicity to mammalian wildlife, but tests with domestic livestock and small laboratory animals indicate that this group is also comparatively resistant. Acute oral LD-50s for mammals > 1,750 mg/kg body weight, and dietary levels of 25 mg/kg (about 1.25 mg/kg body weight) and, for some species, 100 mg/kg body weight and, for some species, 100 mg/kg ter. Proposed criteria for aquatic life protection include < 5 microgm atrazine/L for sensitive species of aquatic flora, and < 11 microgm/L for most species of aquatic flora, and < 11 microgm/L for most species of aquatic flora, and < 11 microgm/L for most species of aquatic flora, and continual than the protection, although it has been suggested that < 7.5 microgm/L in drinking water, and < 0.0375 mg atrazine/kg body weight would pose

The Hazardous and Solid Waste Amendments of 1984 (HSWA) to the Resource Conservation and Recovery Act (RCRA) required EPA to submit a report to Congress concerning those substances identified or listed under Section 3001 of HSWA which are not regulated under this subtitle by reason of the exclusion for mixtures of domestic sewage and other wastes that pass through a sewer system to a publicly owned treatment works (POTW). It has been recommended that additional research, data collection, and analysis be conducted to fill paint formulating industry information gaps concerning the sources and quantities of hazardous waste constituents and their effects on POTWs and the environment. The purpose of this study was to gather information to assist the Agency in deciding whether to develop national effluent limitations guidelines and standards for the industry. The document comprises three studies, undertaken independently, listed as follows: a technical support study; an economic impact study; and an environmental impact study. The environmental impact study was three studies of discharges from four indirect paint plants on POTWs and ultimately on the POTWs' receiving streams. Receiving stream impacts were evaluated by comparing estimated instream pollutant concernations with aquatic life toxic effects levels and EPA Water Quality Criteria developed for human health and aquatic life toxic effects levels and EPA Water Quality Criteria developed for human health and aquatic life toxic effects levels and EPA Water Quality Criteria developed for human health and aquatic life toxic effects levels and EPA water Quality Criteria developed for human health and aquatic life toxic effects levels and EPA water Quality Criteria developed for human health and aquatic life toxic effects levels and EPA water Quality Criteria developed for human health and aquatic life toxic effects levels and EPA water Quality impacts were projected to be minimal. Only two of the 64 evaluated pollutants (benziele to exceed human health criteria at b

SPECIES COMPOSITION OF FISH COMMUNITIES IN NORTHERN WISCONSIN LAKES: RELATION TO PH.

National Fisheries Research Center, La Crosse,

WI. J. G. Wiener, P. J. Rago, and J. M. Eilers. Available from the National Technical Information Service, Springfield, VA 22161, as PB90-132457. Price codes: A03 in paper copy, A01 in microfiche. Report No. EPA/600/D-89/259, 1989. IN: Early Biotic Responses to Advancing Lake Acidification, Butterworth Publishers, Boston. (1988) 17p, 3 fig, 6 tab, 25 ref.

Descriptors: \*Acid rain, \*Hydrogen ion concentration, \*Lake fisheries, \*Limnology, \*Species composition, \*Species diversity, \*Water pollution effects, \*Wisconsin, Acid neutralizing capacity, Acidic lakes, Calcite, Ecosystems, Lakes.

Recent investigations of surface water and precipitation chemistry have aroused considerable concern about the potential effects of acidic precipitation on aquatic ecosystems in the north-central United States. The mean weighted pH of precipitation at two monitoring stations in north-central Wisconsin during 1980, was 4.45 and 4.63, or about 10-14 times, more acidic than normal rainfall—a

theoretical pH of 5.6. Many watersheds in northern Wisconsin have acid soils with low buffering capacities. Consequently, the water of most lakes in these watersheds is very soft and slightly acidic. Analyses of 275 northern Wisconsin lakes during 1979, indicated that 36% of the lakes were susceptible to acidification from acid precipitation as judged by the calcite saturation index; hydrologic type was a major factor affecting susceptibility. Fish communities in circumneutral Wisconsin lakes contained significantly more species than did those in acidic lakes. Common as well as rare fish species occurred with lower frequency in acidic lakes than circumneutral lakes. Differences in species composition and richness of fish communities between acidic and circumneutral lakes did not appear to be related to differences in physical habitat characteristics, past fish migrations or productivity between the two lake groups. Hydrogen ion concentration and related water chemistry characteristics strongly influenced the species composition and richness of fish communities in the lakes. (Lantz-PTT)

HEALTH RISK ASSESSMENT OF TOLUENE IN CALIFORNIA DRINKING WATER.

California Univ., Davis. Dept. of Environmental

Toxicology. R. Reed, W. Reed, L. Beltran, R. Li, and I. Encomienda.

Available from the National Technical Information Service, Springfield, VA. 22161, as PB89-190383. Price codes: A07 in paper copy, A01 in microfiche. Report No. UCD/ET-89/1, March 1989. 133p, 4 fig. 16 tab, 280 ref. State of California Dept. of Health and University of California Interagency Agreement 87-87088.

Descriptors: \*California, \*Drinking water, \*Groundwater pollution, \*Path of pollutants, \*Public health, \*Toluene, \*Water pollution effects, Bioaccumulation, Literature review, Toxicity.

Toluene is used as an octane booster in gasoline and as a solvent base for a number of products. Volatilization from gasoline via spillage and auto exhaust is the principal means by which toluene is released into the environment. The doses of toluene received by populations in California (CA) from water-based sources are difficult to assess because of insufficient data. Three exposure pathways are used to estimate the total dose of toluene received by individuals in dwellings with contaminated tap water: ingestion, inhalation, and dermal contact. Exposure via the three pathways was used to calculate a daily time-weighted lifetime dose factor. Based on groundwater occurrence data on toluene, the estimated total exposed population in California is 25,283, and the estimated average dose per exposed person is 0.00014 mg/kg/d. The three main aims of this document are: (1) to review the existing literature pertinent to the health risk posed by the use of toluene-contaminated drinking water; (2) to estimate the toluene exposure of CA residents based on the most recent data on toluene concentrations in CA drinking water supplies; and (3) to delineate the concentration of toluene in description of the physical and chemical properties of toluene, and its use, environmental fate, and occurrence in CA drinking water. Information regarding absorption, distribution, accumulation, ex-

### Group 5C-Effects Of Pollution

cretion, and mechanisms of toxicity is summarized in Chapter 3. Chapter 4 contains estimates of daily doses that CA residents may receive through oral, dores that CA residents may receive through oran dermal, and inhalation exposures as a result of using toluene-contaminated drinking water. Chap-ters 5 and 6 provide a detailed description of the toxic effects of toluene in model biological systems and in humans to identify the hazards associated with toluene exposure. Chapter 7 presents the no observed adverse effect levels (NOAELs) and lowest observed adverse effect levels (LOAELs) for toluene based on data from acute, subchronic, and chronic toxicity studies in animals and humans. DRINKING WATER CRITERIA DOCUMENT ON XYLENE.

Environmental Protection Agency, Cincinnati, OH. Environmental Criteria and Assessment

Office. Available from the National Technical Information Service, Springfield, VA 22161, as PB89-192314. Price codes: A09 in paper copy, A01 in microfiche. June 1987. 198p, 16 tab, 155 ref.

Descriptors: \*Drinking water, \*Path of pollutants, \*Public health, \*Water pollution effects, \*Xylenes, Biodegradation, Model studies, Organic com-pounds, Toxicity, Volatilization.

Xylene is a dimethylbenzene which occurs in three position isomers: 0-, m-, and p-xylene. Mixed xylene is usually a mixture of the isomers and ethylbenzene. The half-life of xylene in water is about 6 hours, depending on depth, and loss is primarily by evaporation. Xylenes are soluble in water at approximately 175-200 mg/L at environmental temperatures, and the log octanol/water partition coefficients for the isomers range from 2.77 (o-xylene) to 3.20 (m-xylene). In surface waters, xylene volatilization appears to be the dominant removal process, as predicted by an EXAMS model. The volatilization half-lives calculated by the model range from 2.6-11.2 days. Oxi-Xylene is a dimethylbenzene which occurs in three lated by the model range from 2.6-11.2 days. Oxidation does not appear to be significant, nor does photolysis, since the xylenes do not absorb light significantly at wavelengths > 300 nm. Sorption significantly at wavelengths > 300 nm. Sorption will occur, accounting for varying accumulations in the sediments (4.5-70% of the total xylene load from the EXAMS model). Biodegradation may be significant, but appears to be highly variable. A number of experimental studies have been conducted on the toxicity of xylene in humans. A level of near 100 ppm (434 mg/cu m) for about 8 hours/ day for up to 5 days appears to be near a no-effect level for eye and throat irritation. At levels near 300-400 ppm (1300-1730 mg/cu m), reaction time, body balance and dexterity become affected. Most ody obtained and dexterity become affected. Most of the toxic effects of xylene are attributable to the parent compound, but minor metabolites, methylbenzaldehyde and arene oxides have been suggested as toxic intermediates. The appropriate toxicity data in laboratory animals and humans pertinent to the quantification of drinking water health advisory (HA) levels have been reviewed. Data were

insufficient for the derivation of 1-day and 10-day HAs for a child; therefore, the longer-term HA of 36 mg/L is recommended. The longer-term HA 36 mg/L is recommended. The longer-term HA values were determined from a no-observed-effect level in rats treated by gavage for 13 weeks. The values for an adult and a child are 125 and 36 mg/L, respectively. The lifetime HA or drinking water equivalent level (DWEL) was based on a no-observed-adverse-effect level in rats treated by gavage with 250 mg/kg/day, 5 days/week for 103 weeks. The calculated DWEL was 63 mg xylene/L. (Author's abstract) W91-10757

INHIBITION OF NO3(-), NH4(+), AND PO4(3-) UPTAKE IN ANABAENA DOLIOLUM EX-POSED TO A PETROLEUM OIL. North-Eastern Hill Univ., Shillong (India). Dept.

Descriptors: \*Algae, \*Algal physiology, \*Cyanophyta, \*Nutrients, \*Oil pollution, \*Water pollution effects, Ammonium, Chlorophyll a, Mathematical models, Nitrates, Nutrient concentrations, Phos-

Algae and cyanobacteria are being increasingly exposed to high levels of petroleum pollution in aquatic environments. Earlier studies have shown reduced growth of these organisms upon exposure to this pollutant although in some cases, no harm-ful effects and even stimulation, was observed. The effects of petroleum on the kinetics of NO3(-), NH4(+), and PO4(3-) uptake in A. doliolum were analyzed. Assam crude was used as the test oil because its properties and action on other physio-logical processes of this cyanobacteris were stud-ied earlier by the same authors. The agreement ied earlier by the same authors. The aqueous ex-tract of Assam crude inhibited the uptake of these tract of Assam crude innioned the uptake of these compounds and the response was essentially concentration dependent. Inhibition was most severe for the uptake of NH4(+) followed in decreasing order by PO4(3-) and NO3(-). Uptake of nutrients was competitively inhibited and showed no change in V-max (50.64 nmol/microgram chlorophyll a/ hr), but apparent K-m was increased. It is concluded that certain oil components with unknown properties cause competitive inhibition of NO3(-), NH4(+) and PO4(3-) uptake in cyanobacteria. This can be alleviated by increasing the concentration of nutrients in the milieu. Therefore, inhibitory effects of petroleum on nutrient uptake may not pose a serious threat in eutrophic waters rich in nutrients. (Medina-PTT) W91-10825

INDUCTION OF BIOTRANSFORMATION IN THE LIVER OF EEL (ANGUILLA ANGUILLA L.) BY SUBLETHAL EXPOSURE TO DINITRO-O-CRESOL: AN ULTRASTRUCTURAL AND BIOCHEMICAL STUDY. Heidelberg Univ. (Germany, F.R.). Dept. of Zool-

Braunbeck, and A. Volkl.

Ecotoxicology and Environmental Safety EESADV, Vol. 21, No. 2, p 109-127, April 1991. 12 fig. 5 tab, 65 ref. Landesanstat fur Umwelts-chutz, Baden-Wurttemberg, Contract No. 12/

Descriptors: \*Biotransformation, \*Dinitro-ocresol, \*Eel, \*Liver, \*Microscopic analysis, \*Sub-lethal effects, Biochemical tests, Fish physiology, Fishkill,

Structural and functional alterations in hepatocytes of Anguilla anguilla, following a 4-week exposure to 5, 50, and 250 micrograms/liter dinitro-o-cresol (DNOC) were investigated by electron microscopy and biochemistry and compared to liver pathology in eels exposed to the chemical spill into the Rhine river at Basle (Germany) in November 1986. Whereas phenological parameters (growth, condition factor) were unaffected, ultrastructural and biochemical alterations were detectable at greater or equal to 50 and 5 micrograms/liter DNOC,

respectively. Structural modifications included: rounding-up of the nuclei; fractionation and reduc-tion of the rough endoplasmic reticulum; proliferation of the rough endoplasmic reticulum; proliferation of the smooth endoplasmic reticulum; proliferation of the smooth endoplasmic reticulum (SER),
mitochondria, peroxisomes, and lysosomes; bundles of rod-shaped SER profiles; annulate lamellae;
membrane whorls within mitochondria; crystallization of the peroxisomal matrix and glycogen
bodies; glycogen depletion and lipid augmentation.
Structural changes can be correlated to an increase
in hepatic lipid and protein contents as well as
stimulation of mitochondrial (cytochrome c oxidase), peroxisomal (catalase, allantoinase, uricase),
lysosomal (arylsulfatase), and microsomal (esterase) enzymes. An increase in NADPH-cytochrome
c reductase and cytochrome P450 as well as UDPglucuronyltransferase and aryl-sulfotransferase activities in the microsomal fraction document and
induction of hepatic biotransformation as a functional correlate to SER proliferation. Maximum tional correlate to SER proliferation. Maximum tional correlate to SER proliferation. Maximum inducibility of biotransformation enzymes at 50 microgram/liter indicates a biphasic, concentration-dependent reaction to eel liver. Comparison of DNOC-induced effects with liver pathology in eel exposed to the chemical spill in 1986 revealed striking similarities so that DNOC may not be excluded as a possible factor in the fish kill in the Rhine river. (Author's abstract) W91-10826

Descriptors: \*Bioassay, \*Cadmium, \*Ferns, \*Macrophytes, \*Phytotoxicity, \*Toxicity, \*Toxicology, \*Water pollution effects, Biocides, Electron microscopy, Microscopic analysis, Plant growth, Plant pathology, Tissue analysis.

Cadmium is a common water pollutant and its phytotoxicity, ecosystem effects, and accumulation in the food chain are environmental concerns. Aquatic macrophytes offer a convenient test system to study the uptake, translocation, and toxicity of metals under experimental conditions and for extrapolation to ecological field studies. Pterifor extrapolation to ecological field studies. Pteridophytes have received relatively little attention
from environmentalists, hence, the formation of
Cd-binding proteins in cultured vegetative clones
of the aquatic pteridophyte M. minuta was studied
in a static environmental bioassay system as a
function of dose and period of exposure. A transmission electron microscope used to determine the
pathomorphological manifestations of Cd toxicity
showed damage to chloroplasts and tonoplasts as
well as the presence of electron naque eranular snowed damage to chloroplasts and tonoplasts as well as the presence of electron opaque granular deposits. Preliminary evidence based on molecular sieving chromatography indicated the formation of two cadmium-binding proteins of 78 and 33 kilodaltons in the leaf tissue under cadmium stress. Dispersion of tannin bodies in the vacuoles could also be related to Cd treatment. Dose-dependent

changes in the development and differentiation of the juvenile leaves and in the general growth pat-terns were also observed. (Medina-PTT) W91-10829

INITIAL EVALUATION OF DEVELOPMENTAL MALFORMATION AS AN END POINT IN MIXTURE TOXICITY HAZARD ASSESSMENT FOR AQUATIC VERTEBRATES.
Tennessee Univ., Knoxville. Coll. of Veterinary

Medicine

D. A. Dawson, and T. S. Wilke.

Ecotoxicology and Environmental Ecotoxicology and Environmental Safety EESADV, Vol. 21, No. 2, p 215-226, April 1991. 3 fig, 3 tab, 31 ref.

Descriptors: \*Biochemical tests, \*Frogs, \*Hazard assessment, \*Teratogenicity, \*Toxicity, \*Water pollution effects, Animal physiology, Chemical analysis, Embryonic growth stage, Enzymes.

The joint toxic action of three binary mixtures was determined for the embryo malformation endpoint of the aquatic FETAX (frog embryo teratogenesis assay: Xenopus) test system. This system was developed to evaluate chemicals for potential developmental toxicity and teratogenicity, and has appli-cations in aquatic toxicology as well as experimental teratology. Osteolathyrogenic compounds (iso-niazid and beta-aminopropionitrile) and short-chain carboxylic acids (valproic acid and butyric acid), representing separate, distinct modes of action for induction of malformation, were selected for testing in 96-hr, static-renewal tests. Three mixtures were tested for each combination, with each combination being tested on three separate occasions. Using toxic unit analysis, the combination of osteo-lathyrogens and the combination of carboxylic acids produced strictly additive (concentration addition) rates of malformation, while the combina-tion of an osteolathyrogen and a carboxylic acid was less-than-additive (response addition) for in-duction of malformation. Therefore, a develop-mental malformation endpoint may have value for toxicity hazard assessments, especially for ovipa-rous aquatic organisms which may begin organorous aquatic organisms which may begin organo-genesis before completely developing detoxifying enzyme systems. As many polluted freshwater sys-tems are contaminated by more than one undesir-able chemical, the ability to use developmental malformation as an end point in joint toxic action studies represents an additional approach for fur-thering hazard assessment in aquatic toxicology. a-PTT) (Medir

ACUTE AQUATIC TOXICITY OF ALKYL PHENOL ETHOXYLATES, Bayer A.G., Leverkusen (Germany, F.R.). G. Schuurnann.

Ecotoxicology and Environmental Safety EESADV, Vol. 21, No. 2, p 227-233, April 1991. 2 fig, 2 tab, 17 ref.

Descriptors: \*Bioindicators, \*Narcosis, \*Surfactants, \*Toxicity, \*Toxicology, \*Water pollution effects, Aquatic life, Crustaceans, Mathematical models, Organic pollutants, Regression analysis.

The recently derived log K-OW (octanol/water partition coefficient in logarithmic form) increment for a nonterminal oxyethylene (EO) unit was used to calculate a quantitative structure-activity relationship (QSAR) for literature data and the acute to the content of the conten crustacean toxicity of polyoxyethylene surfactants. The resulting log K-OW regression parameters are between the corresponding values for nonpolar and polar narcosis, which supports an interpretaand polar narcosis, which supports an interpreta-tion of the surfactants' aquatic toxicity on the basis of another distinct mode of action. Furthermore, a comparison with calculated water solubility data indicates that for log K-OW > 5 an aquatic toxici-ty decrease due to a solubility limit is expected, which supported by two other sets of toxicity data for nonyl phenol polyethoxylates. According to the present QSAR analysis, the acute aquatic toxic-ity of alkyl phenol ethoxylates can be understood on the basis of a distinct narcosis syndrome. Since on the basis of a distinct narcosis syndrome. Since this anesthetic mode of action also may be valid for other nonionic EO surfactants, the tentative name EO surfactant narcosis syndrome is proposed. Es-

tuarine crustacea appear to be an indicators of the general narcosis toxicity of organic pollutants. Therefore, they are useful as test species for screening purposes. (Medina-PTT) W91-10833

EFFECT OF PESTICIDE TREATMENTS ON NONTARGET ORGANISMS IN CALIFORNIA RICE PADDIES.

ty, Urea pesticides.

An application of triphenyltin hydroxide at 1.16 kg Al/ha (active ingredient per hectare) to rice fields for stem rot (Sclerotium oryzae) control resulted in a significant reduction of 57% of the invertebrate taxa and 67% fewer individuals based on two collecting methods that sampled the nekton, neustron, and benthos. Population of herbivores, carnivores and filter feeders were sharply reduced after treatment, and most remained so through the 28th day following application. By day 50 many of the winged species recovered in both numbers and diversity. However, recovery of benthic organisms was slower or not at all for most Crustacea. An initial reduction followed by a strong resurgence was noted for the mosquito Culex tarsalis, which was probably due to the significant reduction of the predaceous species. Two benzoylphenyl ureas, diflubenzuron and triflumuron, were evaluated in California rice fields to determine their ecological impact on populations of nontarget organisms. impact on populations of nontarget organisms.

Modified minnow traps, drag net, and kellen dredge sampling were used in the collecting. Nondredge sampling were used in the collecting. Non-target populations were sampled continuously throughout much of the 1985 and 1986 rice grow-ing season. Total collections of non-targets showed only two Cypris species of seed shrimp crustaceans were significantly (P<0.05) reduced over time due to either chemical. One predaceous water boat-nan, Corisella decolor, showed the opposite pat-tern in that populations were significantly (P<0.05) lower in the control. Significant differ-ences were not observed in species diversity or (15 < 0.02) lower in the control. Significant differences were not observed in species diversity or between treatments when grand means for all species by sampling device were calculated. A total of 35 families and 58 taxa were collected from these two studies. (Author's abstract)

DIOXIN CONTAMINATION AND GROWTH AND DEVELOPMENT IN GREAT BLUE HERON EMBRYOS.

The reproductive success of great blue heron colonies on the Strait of Georgia, British Columbia (Canada), has been monitored since 1983. A colony of this bird near a pulp mill failed to fledge young in 1987, had a concurrent sharp increase in polychlorinated dibenzo-p-dioxin (PCCD) and polychlorinated dibenzo-p-dioxin (PCCD) levels in their eggs. In 1988, the hypothesis that the PCDD and PCDF contamination caused reproductive failure by increasing mortality of the heron embryos in ova was tested. Pairs of great blue heron eggs were collected from three British Columbia colonies

with low, intermediate, and high levels of dioxin with low, intermediate, and high levels of dioxin contamination: Nicomeki, Vancouver and Crofton, respectively. One egg of each pair was incubated under laboratory conditions at the University of British Columbia while the other egg was analyzed for PCCDs and PCDFs. All incubated eggs were fertile. All eggs from the Nicomeki colony hatched, while 13 of 14 eggs from Vancouver and 12 of 13 eggs from Crofton hatched. Subcutaneous edgma was observed in 4 of 12 chicks from Crofton of the process of th edema was observed in 4 of 12 chicks from Crofton and 2 of 13 chicks from Vancouver. No edema was seen in the chicks from Nicomeki. There was a was seen in the chicks from Nicomeki. There was a small, but significant, negative regression of plasma calcium concentration, yolk-free body weight, tibia length, wet, dry, and ash weight, beak length, and kidney and stomach weight of the hatched chicks with the tetrachlorodibenzo-p-dioxin (TCDD) level of the paired eggs. Fewer down follicles were present on the heads of TCDD-contaminated chicks. Hence while dioxins did not cause mortality of the hence surheve in over the depression. ty of the heron embryos in ovo, the depression of growth and the presence of edema are suggestive that dioxins at the levels found in the environment have an adverse effect on the development of great blue heron embryos. (Author's abstract)

SUBCHRONIC HEPATOTOXICITY OF SE-LENOMETHIONINE INGESTION IN MAL-LARD DUCKS

Selenium (Se) can reach toxic levels in aquatic environments from leaching of agricultural soils, fly ash from coal-fired power plants, and mining of phosphates and metal ores. A study was designed to examine the effects in adult mallards (Anas platyrhynchos) of subchronic dietary exposure to release a form of Sa found in vaccinations. platyrnynchos) or subchrome chetary exposure to selenomethionine, a form of Se found in vegeta-tion. Two-year old male mallards received a con-trol diet (0.2 ppm Se) or diets containing 1, 2, 4, 8, 16, or 32 ppm Se as selenomethionine for 14 wk. Se accumulated readily in the liver in a dose-depend-16, or 32 ppm Se as selenomethionine for 14 wk. Se accumulated readily in the liver in a dose-dependent manner, reaching a mean concentration of 29 ppm (wet weight) in the 32 ppm group. Dietary Se of 2 ppm or greater increased plasma glutathione peroxidase activity. Mortality (10%) and histopathological effects, including bile duct hyperplasia and hemosiderin pigmentation of the liver and spleen, occurred in the 32 ppm group. These histopathological effects were accompanied by lower hemoglobin concentrations (16 and 32 ppm groups) and hematocrit (32 ppm group), and elevated plasma phosphatase activity (32 ppm group) indicative of cholestatic liver injury. Other manifestations of hepatotoxicity included significant linear dose responses for hepatic oxidized glutathione (GSSG) concentrations and ratio of GSSG to reduced glutathione (GSH). Means for both of these responses differed from control in groups receiving 8-32 ppm Se. Mean hepatic GSH and malondialdehyde (a measure of lipid peroxidation) concentrations were significantly elevated in the 16 and 32 ppm groups. Subchronic effects of selenomethionine, which occurs in vegetation, are of particular interest with respect to the health of wild aquatic birds in seleniferous locations. MODIFICATION OF BENTHIC COMMUNITY STRUCTURE IN RESPONSE TO ACID-IRON WASTES DISCHARGE.

Marine Ecological Surveys Ltd., Faversham (England)

iana). R. C. Newell, D. W. Maughan, M. W. Trett, P. F. Newell, and L. J. Seiderer. Marine Pollution Bulletin MPNBAZ, Vol. 22, No. 3, p 112-118, March 1991. 6 fig, 20 ref.

Descriptors: \*Acidic water, \*Benthic fauna, \*Industrial wastewater, \*Iron, \*Quebec, \*South Africa, \*Wastewater pollution, \*Water pollution effects, Canada, Coastal waters, Invertebrates, Rivers, St Lawrence River, Titanium dioxide in-

Surveys of the impact of acid-iron wastes from the titanium dioxide industry on benthic community titanium dioxide industry on benthic community structure were carried out at a number of sites world-wide. Results are presented for an outfall into the freshwaters of the St. Lawrence River near Quebec, Canada and for an outfall into the coastal waters of the Indian Ocean near Durban, South Africa. The results suggest that it is the metallic components of the dispersing neutralized effluent, rather than acidity, which are responsible for changes in invertebrate community structure along the axis of dispersion wastes. This implies that elimination of biological impact may best be achieved by a reduction of trace metals either in the feedstock or by removal from the effluent stream. Previous surveys suggest that the concenstream. Previous surveys suggest that the concentrations of copper and manganese in the sediments have no consistent relationship with the zone of biological impact. The concentrations of zinc within the zone of biological impact; however, within the zone of biological impact; however, show a remarkable similarity in both marine and freshwater systems and indicate that values in excess of 250-300 mg/kg are associated with a modification of benthic community structure. Corresponding values for lead are 20-30 mg/kg, vanadium 40-60 mg/kg, chromium 70-100 mg/kg and iron 3.0-4.0 ppt. This suggests that these metallic residues have a relative impact of Pb > V > Cr > Zn > Fe, although there is no information at present on the extent of the impact which one or a present on the extent of the impact which one, or a combination of these metallic residues, is exerting on the benthic community structure. The acid content has long been targeted as the important component of acid-iron wastes from the titanium dioxide industry. However, numerous studies have shown the impact extends beyond the zone of reduced pH. A 10-minute sperm test, using zone of reduced pH. A 10-minute sperm test, using the gametes of the sea urchin Echinometra mathaei on components of a typical acid-iron effluent, showed that while the acid was rendered non-toxic at less than 5000 dilutions, the acid-iron mixture required in excess of 100,000 dilutions to render it non-toxic. Iron hydroxide caused clumping of the sperm, thus effectively inhibiting fertilization in seawater, with serious implications for all species practicing external fertilization. EFFECTS OF LINEAR ALKYLBENZENE SUL-PHONATE (LAS) ON SKELETAL DEVELOP-MENT OF SEA URCHIN EMBRYOS (PARA-CENTROTUS LIVIDUS LMK), Padua Univ. (Italy). Dept. of Biology. M. Bressan, M. G. Marin, and R. Brunetti.

Water Research WATRAG, Vol. 25, No. 5, p 613-616, May 1991. 6 fig. 31 ref.

Descriptors: \*Animal growth, \*Detergents, \*Echinoderms, \*Linear alkyl sulfonates, \*Toxicity, \*Toxicology, \*Water pollution effects, Calcium, Chronic toxicology, Embryonic growth stage, Inhibition, Surfactants.

Linear alkylbenzene sulphonate (LAS) acts on the zygotes of the sea urchin Paracentrotus lividus, inducing total inhibition of skeletal development at concentrations higher than 0.45 ppm and a signifi-cant decrease at concentrations of 0.30 ppm. The effect of the surfactant is maximum at the end of gastrulation, when Ca uptake is very high, presum-ably related to the beginning of skeletal growth. This suggests that in the environment the sequestering action of LAS on Ca may significantly affect the availability of Ca for morphogenesis. Nevertheless, the experimental data suggest that the toxic action of LAS is also exerted at levels other than those involved in Ca uptake. (Author's W91-10891

ROLE OF PHOSPHORUS CYCLING IN ALGAL METABOLISM AND ALGAL SUCCES-SION IN LAKE DONGHU, CHINA.

Academia Sinica, Luojiashan (China). Inst. of Hydrobiology.

J. Wang, and J. K. Liu.

Archiv fuer Hydrobiologie AHYBA4, Vol. 120, No. 4, p 433-445, February 1991. 7 fig, 4 tab, 23

Descriptors: \*Algae, \*Eutrophication, \*Lakes, \*Limnology, \*Metabolism, \*Phosphorus, \*Water pollution effects, Algal blooms, Aquatic life, Biomass, \*China, Enrichment, Lake Donghu, Nutrients, Photosynthesis, Success

The role of phosphorus cycling in algal metabolism was studied in shallow Lake Donghu in Wuhan, China, using the methods of measuring cell percent of C, N and P, and calculating nutrients uptake rate by algal photosynthesis. The turnover time of phosphorus in phytoplankton metabolism ranged from 0.75-5.0 days during 1979-1986. The available P was 0.176 (plus or minus 0.156) g/cm m (mean plus or minus standard deviation) in The available P was 0.176 (plus or minus 0.156) g/cu m (mean plus or minus standard deviation) in 1982 and 0.591 (plus or minus 0.24) g/cu m in 1986. The relationship between P and biomass or P/B ratio (Y) and Total-p (X:mg/l) was described by the following regression equation Y = 1.163 + 0.512logX (r = 0.731, P < 0.001). The dynamics of algal biomass and algal species succession were monitored as the indicators of environmental enrichment. The small-sized algae have replaced the blue-green algae as the dominant species during 1979-1986. The small-sized algae include Merismopedia glauca, Cryptomonas ovata, Cryptomonas erosa, and several species of Cyclotella. There has been drastic decrease in algal biomass and an obvious increase in the P/B ratio. A nutrient competi-tion hypothesis is proposed to explain the reason for the disappearance of blue-green algae bloom. The drastic change in algal size and the high P/B ratio (reaching a maximum mean daily ratio of 1.09 in 1986) may suggest a transition of algal species from K-selection to r-selection in Lake Donghu. EFFECTS OF COPPER AND TRIBUTYLTIN ON STRESS PROTEIN ABUNDANCE IN THE ROTIFER BRACHIONUS PLICATILIS.

University of South Florida, Tampa. Dept. of Biol-

ogy. B. J. Cochrane, R. B. Irby, and T. W. Snell. Comparative Biochemistry and Physiology (C) CBPCEE, Vol. 98, No. 2/3, p 385-390, 1991. 6 fig,

Descriptors: \*Aquatic animals, \*Copper, \*Heavy metals, \*Organotin compounds, \*Proteins, \*Rotifers, \*Toxicity, \*Toxicology, \*Water pollution effects, Genetics, Immunochemistry, Kinetics.

Evidence has accumulated in many species that very specific changes in patterns of gene expres-sion occur in response to toxicant exposure. The question relevant to environmental toxicology is question relevant to environmental toxicology is whether changes in expression of such genes are suitable for assessing toxicity. One experimental approach is to examine a response that is characteristic of a wide variety of organisms in a species for which classic toxicological measures can be readily obtained. This approach was employed by examinobtained. This approach was employed by examing the expression of a particular stress protein of 58,000 Da (SPS8) in the marine rotifer Brachionus plicatilis. Exposure of Brachionus plicatilis to elevated temperature resulted in the synthesis of a number of proteins, including a prominent one of 58,000 Da (SPS8). This protein is immunologically cross-reactive with the 65,000 Da heat shock protein of the moth Helitothis viercess which is tein of the moth Heliothis virescens, which is a member of a highly conserved family of mitochondrial proteins. Exposure of rotifers to sublethal doses of CuSO4 leads to a 4 to 5-fold increase in abundance of SP58, with maximum increase occurring at a does that it constitutions to the control of abundance of SPS8, with maximum increase occurring at a dose that is approximately 5% of the LC50 for that compound. A similar response was seen with tributylin (TBT). Kinetics of induction were sigmoidal, with induction occurring in the range of 20-30 microgram/L. No response was observed when rotifers were exposed to aluminum chloride, mercury chloride, pentachlorophenol, sodium arsenite, sodium azide, sodium dodecyl sulfate, or zinc chloride. These results indicate that changes in stress protein abundance may prove useful as a biomarker of exposure to particular toxicants. (Agostine-PTT)

DECREASED NOREPINEPHRINE AND EPINEPHRINE CONTENTS IN CHROMAFFIN TISSUE OF RAINBOW TROUT (ONCORHYNCHUS MYKISS) EXPOSED TO DIETHYLDITHIOCARBAMATE AND AMYLXANTH-

Uppsala Univ. (Sweden). Dept. of Zoophysiology. G. E. Nilsson, and M. Block.

Comparative Biochemistry and Physiology (C) CBPCEE, Vol. 98, No. 2/3, p 391-394, 1991. 2 fig, 1 tab, 19 ref.

Descriptors: \*Carbamate pesticides, \*Epinephrine, \*Fish physiology, \*Norepinephrine, \*Toxicity, \*Toxicology, \*Trout, \*Water pollution effects, Enzymes, Path of pollutants.

A study was conducted to determine if a diethyl-dithiocarbamate (DDC) or amylxanthate (AX) exposure decreases the amounts of norepinephrine (NE) and epinephrine (E, which is synthesized from NE) present in the head kidney (pronephros) of rainbow trout. The head kidney contain chromaffin tissue which synthesize and store NE and E and subsequently release these stress hormones into the blood. Rainbow trout (Oncorhynchus mykiss) were exposed to 0.5 or 5.0 micro M of DDC or AX for 24 hours. Both DDC (0.5-5.0 microM) and AX (5.0 microM) significantly decreased NE and E levels in the head kidney as well as the quotients epinephrine/dopamine and/or norepinephrine/dopamine the results of the synthesis of NE and E from dopamine. It results probably reflect an inhibition of dopamine-beta-hydroxylase, the enzyme responsible for the synthesis of NE and E from dopamine. study was conducted to determine if a diethylsible for the synthesis of NE and E from dopamine. It is concluded that an exposure of fish to these complexing agents could disturb physiological processes controlled by catecholamines. Diethyl-dithiocarbamate may prove to be a valuable pharmacological tool for the study of catecholamine function in fish. (Agostine-PTT)

## OZONE, ACIDIC PRECIPITATION, AND SOIL MG EFFECTS ON GROWTH AND NUTRITION OF LOBLOLLY PINE SEEDLINGS.

Tennessee Valley Authority, Norris. Cooperative

G. S. Edwards, N. T. Edwards, J. M. Kelly, and P. A. Mays. Environmental

and Experimental Environmental and Experimental Botany EEBODM, Vol. 31, No. 1, p 67-78, January 1991. 4 fig, 6 tab, 39 ref. Electric Power Research Insti-tute Contract RP-2799-2, U.S. Department of Energy Contract DE-AC05-84OR21400.

Descriptors: \*Acid rain, \*Air pollution effects, \*Magnesium, \*Ozone, \*Pine trees, \*Plant growth, \*Soil-water-plant relationships, Conifers, Leaching, Nutrients, Nutrition, Precipitation, Seedlings, Simulated rainfall, Soil chemistry, Soil types, Throughfall

The height, diameter, biomass, and nutrient con-centration and content were determined for lobloid ly pine (Pinus taeda L.) seedlings grown at two levels of soil Mg and exposed to chronic levels of czone and simulated acidic precipitation. Nutrient contents in precipitation and throughfall were also contents in precipitation and throughfall were also determined. Seedlings were planted in a sandy loam soil (Lilly series) having approximately 15 or 35 mg/kg Mg and were exposed to sub-ambient, ambient, or twice ambient concentrations of ozone in open top chambers from May to October of 1984. Seedlings also received simulated rainfall at pH 3.8 or 5.2 in volumes equivalent to ambient rainfall. After two growing seasons, height and diameter were significantly greater for seedlings exposed to unb-ambient. growing seasons, height and diameter were significantly greater for seedlings exposed to sub-ambient and twice ozone than for seedlings exposed to ambient ozone. Biomass of all seedling components was progressively reduced with increasing ozone concentrations. Net throughfall nutrient contents and foliar nutrient contents were not significantly affected by precipitation pH treatments, indicating that foliar leaching was not accelerated by increasing the acidity of precipitation from pH 5.2 to 3.8. Throughfall and foliar nutrient contents were not significantly affected by ozone treatments, and no significant ozone x precipitation pH interactions occurred, indicating that after two growing seasons ozone did not act to exacerbate foliar leaching. Seedlings grown in soil having 15 mg/kg Mg sons ozone did not act to exacerbate foliar leaching. Seedlings grown in soil having 15 mg/kg Mg exhibited significantly reduced Mg concentrations and contents in all components, but seedling growth was not significantly affected by this treatment. Descriptors: \*Acid rain effects, \*Corn, \*Drought effects, \*Moisture stress, \*Plant-water relation-ships, \*Stomatal transpiration, Acid rain, Conduct-ance, Greenhouses, Leaves, Plant growth, Simulated rainfall

Studies were conducted to determine if simulated Studies were conducted to determine it simulated acidic rain (SAR) could predispose Zea mays L. cv. B73 x Mo17 to drought stress by altering cuticular and stomatal conductance. Experiments were conducted with field-grown plants in 1986, 1987, and 1988, and with greenhouse-grown plants

in 1987 and 1988. Plants were treated with SAR of pH 5.0 or 3.0 twice weekly. In the field two droughts, approximately 2 weeks in duration, were imposed by withholding water; one followed silking and the other occurred during grain fill. In the greenhouse one 10-day drought was imposed following 3-4 weeks of SAR treatments, which began at emergence. During the drought stress, cuticular and stomatal conductances were measured. Drought significantly decreased cuticular conductance in the field on 3 days in 1986. 2 days in 1987, and 3 days in 1988. Rain pH had no effect on cuticular conductance, and there was a significant drought-by-pH interaction on day 1 in 1987 in cuticular conductance, and there was a significant drought-by-pH interaction on day 1 in 1987 in which plants treated with rain of pH 3.0 under non-drought conditions had the highest cuticular conductance. Stomatal conductance was significantly decreased by drought on 5 days in 1986, 8 days in 1987 and on 1 day in 1988. Rain pH 3.0 increased stomatal conductance on 2 days in 1987 increased stomatal conductance on 2 days in 1987 and decreased stomatal conductance on 1 day in 1988. There were no significant interactions. Greenhouse results showed decreased cuticular conductance as drought progressed with no interactive effects due to SAR. In 1988, plants treated with SAR of pH 5.0 had a higher cuticular conductance than plants treated with pH 3.0 for 2 days of the drought. Drought was a more significant physiological stress for cv. B73 x Mo17 of Z. mays than was SAR. (Author's abstract)

### LC-50 ESTIMATES AND THEIR CONFIDENCE INTERVALS DERIVED FOR TESTS WITH ONLY ONE CONCENTRATION WITH PAR-TIAL EFFECT.

Institute of Environmental Sciences TNO. Delft

N. van der Hoeven

Water Research WATRAG, Vol. 25, No. 4, p 401-408, April 1991. 3 fig, 2 tab, 3 ref, 2 append.

Descriptors: \*Confidence intervals, \*Lethal limit, \*Median tolerance limit, \*Statistical methods, \*Toxicology, \*Water pollution effects, Ecotoxicology, Lethal concentrations, Mathematical studies, Maximum likelihood estimators, Mortality, Statisti-

When several test concentrations lead to a partial mortality with a concentration-effect relationship the maximum likelihood estimators (MLE) of the various parameters and their confidence intervals various parameters and their confidence intervais can be calculated using a linear approximation. However, in many ecotoxicological experiments partial mortality is only observed at one test concentration, even though the ratio between the test concentrations is fairly small. In that case the calculation of the MLEs of the parameters, and even more of their confidence intervals is not straight-forward. The likelihood isoclines appear to have a rather unusual form, with the MLE on the border rather unusual form, with the MLE on the border of each confidence set with likelihood greater than some arbitrary value. The likelihood-ratio basic confidence intervals are calculated. It is concluded that linear approximation fails to determine the likelihood based confidence interval for the LC-50 parameter (the concentration at which half of the test animals are killed by the test substance) in a toxicity experiment with only one concentration causing mortality. An equation for this confidence causing mortality. An equation for this confidence interval is derived given a log-logistic concentration response relation. A table of the 95 and 99% confidence intervals is given for the case that partial survival occurs only at one concentration, under the condition that a fixed number of animals is used at each test concentration and a constant ratio is used between the test concentrations.

A discrete-site model of ion-binding by humic sub-A discrete-site model of ion-binding by humic sub-stances (HS), incorporating a description of elec-trostatic effects, is evaluated with analytical data for surface waters of acid pH (3.5-6.5). After opti-mization of the model by adjustment of the bind-ing-site content of the HS, the root-mean-square deviation (RMSD) between measured and calculat-ed concentrations of organically-complexed mono-meric aluminum is 1 microM for a range of mea-sured values of 0.1-9.0 microM (108 samples from 12 different locations). The optimization indicates 12 different locations). The optimization indicates that the dissolved organic matter of natural waters is only about 50% as 'active' (in the sense of ion-binding) as isolated HS. The model, optimized for Al-binding, also accounts for the contributions of HS to ionic balance; for 139 samples (from 8 Its to folio balance; for 139 samples (from 6 locations) with dissolved organic carbon concentrations in the range 4.6-43.0 mg/L, and using measured pH as input for the computations, the mean calculated ration of cations to anions was 1.03, with a standard deviation of 0.11. For the 1.03, with a standard deviation of 0.11. For the same 139 samples, pH values were also calculated, using total measured anion concentration as inputs. The RMSD in pH was 0.35 for all samples, but only 0.18 for the 56 samples of pH < or = 4.5. Statistical analyses indicate that inadequacies in model assumptions, including the estimation of concentrations of HS in water samples, account for about one-third of the discrepancy between measured and calculated organically-complexed monomeric aluminum; the remaining two-thirds is explained by errors in input data and measured organically-complexed monomeric aluminum. In the case of pH prediction, no model inadequacy is case of pH prediction, no model inadequacy is apparent, because of the high sensitivity of the calculations to errors in input data. # FACTORS AFFECTING THE RELATIONSHIP BETWEEN THE NBOD VALUES AND THE AMOUNTS OF NITROGENOUS POLLUT-ANTS: A FIELD STUDY ON THE LEE RIVER.

Beijing Univ. (China). Dept. of Geography. J. Deai, T. Yida, Y. Gong, Z. Jianrong, and S

Water Research WATRAG, Vol. 25, No. 4, p 485-489, April 1991. 1 fig, 4 tab, 12 ref. National Science Foundation Project (86) GKJD 005.

Descriptors: \*Biological oxygen demand, \*Nitro-gen compounds, \*Nutrient transport, \*Path of pol-lutants, \*Stream pollution, \*Water pollution ef-fects, China, Field tests, Hydrogen ion concentra-tion, Hydrologic aspects, Statistical analysis, Water

The relationships between the nitrogenous biological oxygen demand (NBOD) values, the amounts of nitrogenous pollutants and the effects of some environmental factors on these relationships were investigated. The relationship between the NBOD and the oxidizable nitrogenous pollutants in the Lee River, near Tianjin, China, has been determined to be dependent upon the hydrological control of the mined to be dependent upon the hydrological con-ditions. When there is no water discharge (NWD) from the upper reservoir, this relationship is quite clear and definite, but under water discharge (WD) conditions, this relationship is not well defined. Mean ratios of NBOD's to BOD's are 0.620 for the NWD case and 0.379 for the WD case, with maximum ratios of 0.944 and 0.643, respectively. Differences between these two cases are caused mainly by the variations of several factors such as concentration of oxidizable nitrogen compounds, an abun-dance of nitrifying organisms, pH and velocity and depth of water. The hydrological conditions play an important role in these variations. (Agostine-PTT W91-10940

ACUTE PHOTOTOXICITY OF HARBOR AND TRIBUTARY SEDIMENTS FROM LOWER LAKE MICHIGAN.
Illinois Univ. at Urbana-Champaign. School of

Journal of Great Lakes Research JGLRDE, Vol. 17, No. 1, p 51-56, 1991. 6 fig, 15 ref.

Descriptors: \*Lake Michigan, \*Lake sediments, \*Light effects, \*Photoactivation, \*Toxicity, \*Toxicology, \*Water pollution effects, Dredging, Great Lakes, Photolysis, Polycyclic aromatic hydrocarbons, Shallow water, Waterfleas.

A number of recent findings suggest that the inter-action between sediment pollutants and sunlight might pose a hazard which has been previously might pose a hazard which has been previously unsuspected; the phototoxicity of polycyclic aromatic hydrocarbons (PAHs), together with their accumulation in sediments, suggest that dredging and other disturbances may pose a presently unrecognized environmental hazard. To test this, sediments contaminated with PAHs were collected from sites on lower Lake Michigan (the Grand Calumet River, the Indiana Harbor Canal, and Waukegan Harbor). The phototoxicity of liquid-phase elutriates was tested using Daphnia magna-phototoxicity was found in Grand Calumet River and Indiana harbor elutriates, both in sunlight and 354 nm near-uv. None of the elutriates was toxic in the absence of light. These results reveal an importhe absence of light. These results reveal an important and previously unsuspected hazard to sha water environments near dredging sites, and de-scribe simple methods to detect phototoxicity which will be of value in the establishment of sediment quality criteria. SIMULATED HYDROLOGIC EFFECTS OF CLIMATIC CHANGE IN THE DELAWARE RIVER BASIN.

Geological Survey, West Trenton, NJ. M. A. Ayers, D. M. Wolock, G. J. McCabe, and

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 587-594, 5

Descriptors: \*Climatic changes, \*Delaware River Basin, \*Global warming, \*Hydrologic budget, Basin, "Global warming, "Hydrologic budget, \*Simulation analysis, Evapotranspiration, Model studies, Runoff, Snow, Streamflow, Water supply.

Projections of climatic change indicate uncertainty regarding future availability of water in the Dela-ware River basin. Simulations of the effects of atmospheric warming on runoff indicate that a decrease in snow accumulation in the northern part of the basin, and an increase in evapotranspiration or the basin, and an increase in evapotranspiration throughout the basin, could change the temporal distribution of runoff and reduce total annual streamflow by as much as 25% given current precipitation patterns. An increase in precipitation of about 3% would be needed to counteract decreases in runoff that would result from each degree Celsi-

us warming. Simulations indicate that without more reliable estimates of regional precipitation and warming patterns, the future direction and magnitude of basin streamflow changes cannot be determined precisely. (See also W91-11003) (Author's abstract)

GREAT LAKES HYDROLOGICAL IMPACTS OF 2XCO2 CLIMATE CHANGE. National Oceanic and Atmospheric Administra-tion, Ann Arbor, MI. Great Lakes Environmental Research Lab. T. E. Croley.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 595-604, 3 fig,

Descriptors: \*Great Lakes, Basin, \*Hydrologic budget, \*Carbon dioxide, \*Climate change, \*Precipitation, \*Global warming, Model studies, Atmospheric circulation, Air temperature, Evapotranspiration, Snowpack, Runoff, Ice, Soil water.

The Great Lakes Environmental Research Labora-In cyfeat Lakes Environmental Research Labora-tory considered climate change impacts on North American Great Lakes hydrology by using recent atmospheric general circulation model (GCM) sim-ulations of a doubling of atmospheric CO2, avail-able from the Goddard Institute for Space Studies. Changes were made in historical meteorological changes were made in insortical interotological data, similar to the changes observed in the GCM, and the impact of the changed data in hydrology models for basin moisture storage and runoff, overlake precipitation, and lake heat storage and evaporation were observed. While precipitation changes are uncertain, higher air temperatures generally increase basin evapotranspiration which decreases the snowpack, lowers runoff, shifts runoff peaks, and reduces soil moisture. There are larger amounts of heat resident in the deep lakes reducing buoyancy-drive turnovers of the water column, lowering ice formation, and increasing lake evaporation. The carbon dioxide concentration in the atmosphere has increased by about 25% over the last 150 years and will continue to increase as a result of years and will continue to increase as a resuit of fossil fuel combustion. Enhancement of the atmospheric greenhouse effect by elevated levels of carbon dioxide and other trace gases may, over the next century, increase global average surface air temperature by a few degrees Celsius to levels unprecedented in human history. Even eliminating emissions of carbon dioxide will not prevent global climate change because the combined greenhouse effect of less abundant but radiatively important gases such as methane and chlorocarbons is likely gases such as inclinate and chilorocarbons is likely to be as large as the impact of projected increases in carbon dioxide concentration. Quantitative esti-mates of future warming that could result of continued increases in greenhouse gas concentrations come from sophisticated mathematical models,

which are the modern climatologists' primary prognostic tool. The current limitations and uncer-tainties in these model results, however, prevent definitive predictions of the regional climatic re-sponses that make up the projected global change. Deficiencies in the historical climate record prevent confirmation of the climate model predictions, but future research offers the potential for im-proved understanding. EFFECTS OF ACID RAIN ON EPIPHYTIC ORCHID GROWTH.

Barry Univ., Miami Shores, FL. Div. of Biological and Biomedical Sciences.

J. K. Frei, C. Orenic, N. Smith, and H. Jeffer IN: Environmental Problems and Solutions: Greenhouse Effect, Acid Rain, Pollution. Hemisphere Publishing Corporation, New York. 1990. p 149-163. 3 tab, 24 ref.

Descriptors: "Acid rain, "Acid rain effects, "Epi-phytes, "Orchids, "Plant growth, "Water pollution effects, Big Cypress Swamp, Florida, Hydrogen ion concentration, Path of pollutants, Plant-water relationships, Simulated rainfall.

The Big Cypress Swamp in South Florida has a high diversity level of subtropical flora and fauna. Among the species of subtropical vegetation occurring in this area are many epiphytic plants which are vulnerable to atmospheric inputs. Some preliminary evidence indicates that this general area may be experiencing elevated concentrations of gaseous and particulate air pollutants, but very little is known about the potential impact on biological resources. The effects of simulated acid rain logical resources. The effects of simulated acid rain were tested at several pH levels to evaluate impact on growth and development of the epiphytic orchid plant Encyclia tampensis. The sixty plants used were collected from the Fakhahatchee Strand located within the Big Cypress Swamp. Plants used were mature plants, intermediate sized plants and young seedlings, which were exposed to the pH ranges of simulated acid rain (pH 2.5, 4.0, 5.6) for a period of six months. Observations were made on the number and conditions of flower spikes and flower buds; number and conditions of nower spikes and flower buds; number and condition of new and old leaves; and the general condition of the plant. The results indicated a negative effect on the growth rate of plants exposed to varying levels

RELATIONSHIP OF REGIONAL WATER QUALITY TO AQUIFER THERMAL ENERGY STORAGE. Battelle Northwest Labs., Richland, WA.

Battele Facilit Vorthwest Loss, Richiand, WA. R. D. Allen, and J. R. Raymond. IN: Environmental Problems and Solutions: Greenhouse Effect, Acid Rain, Pollution. Hemi-sphere Publishing Corporation, New York. 1990. p 415-435. 1 fig, 3 tab, 26 ref.

Descriptors: \*Aquifer management, \*Groundwater quality, \*Heat storage, \*Model studies, \*Permeability, \*Thermal energy, \*Water pollution sources, Corrosion, Evapotranspiration, Hydrogen ion concentration, Ion exchange, Mineral oxidation, Precipitation, Rock properties, Salinity, Water resources development.

Aquifer thermal energy storage (ATES) involves injection and withdrawal of temperature-conditioned water into and from a permeable water-bearing formation. The groundwater quality and associated geological characteristics were assessed as they may affect the feasibility of ATES system as they may affect the feasibility of ATES system development in any hydrologic region. Seven physical and chemical mechanisms may decrease system efficiency: particulate plugging, chemical precipitation, clay mineral dispersion, piping corrosion, aquifer disaggregation, mineral oxidation, and the proliferation of biota. Factors affecting groundwater quality are pressure, temperature, pH, ion exchange, evaporation/transpiration, and commingling with diverse waters. Modeling with the MINTEQ code showed three potential reactions: precipitation of calcium carbonate at raised tions: precipitation of calcium carbonate at raised temperatures; solution of silica at raised temperature followed by precipitation at reduced tempera-tures; and oxidation/precipitation of iron compounds. Low concentrations of solutes are generally favorable for ATES. Near-surface waters in high precipitation regions are low in salinity. Groundwater recharged from fresh surface waters also has reduced salinity. Rocks least likely to react aiso has reduced sainnty. Rocks least likely to react with groundwater are sliceous sandstones, regoliths, and metamorphic rocks. Limestone, dolomite, shale and basalt contain reactive minerals. Intrusive rocks may yield alkalis, alkaline earths, and iron by hydrolysis of feldspathic and ferromagnesian minerals. On the basis of known aquifer hydrology, ten US water resource regions are can-didates for selected exploration and development, all characterized by extensive silica-rich aquifers. KINETICS OF CHEMICAL WEATHERING IN B HORIZON SPODOSOL FRACTION, Iowa Univ., Iowa City. Dept. of Civil and Envi-ronmental Engineering. S. R. Asolekar, R. L. Valentine, and S. L.

Schnoor.

Water Resources Research WRERAQ, Vol. 27, No. 4, p 527-532, April 1991. 5 fig. 1 tab, 26 ref. USEPA Watershed Manipulation Cation Resupply Grant CR-813634-01.

Descriptors: \*Acid rain, \*Acid rain effects, \*Kinetics, \*Maine, \*Soil horizons, \*Weathering, Geochemistry, Hydrogen ion concentration, Soil chemistry, Soil properties, Solute transport.

Knowledge of the kinetics of chemical weathering Knowledge of the kinetics of chemical weathering is central to understanding the global hydrogeochemical cycle whereby weatherable minerals in rocks transform to soils, sediments, and ultimately to sedimentary rocks. Studies on a B horizon soil from Maine were conducted to determine the dependence of the weathering rate on hydrogen ion concentration in soil solution. Effects of soil concentration and solution chemistry on chemical weathering rate also were investigated. Studies

were conducted using a laboratory stat pH-stat semicontinuous reactor at pH 2.7 and pH 3.5 for two concentrations of B horizon soil. Homog-enized B horizon soil in the size range 63-125 micrometer was washed in deionized water and acetone and used without further treatment. Results obtained with titrations of 10, 30, and 100 g/L solution obtained with utrations of 10, 30, and 100 g/L of soil at a constant pH of 2.7 suggest that the weathering rate, expressed as microequivalents of H(+)/hr/g soil, does not depend on the soil concentration in the pH-stat reactor. To test the effect of solute concentration on weathering rate, experi-ments were performed at two different concentrations of accumulated solutes. Weathering rates were the same at the two solute concentrations, indicating that significant back reactions likely were not occurring. The weathering rate at pH 2.7 was estimated to be in the range 0.53-0.93 microequivalents H(+)/hr/g soil, at pH 3.5 at 0.36 microequivalents H(+)/hr/g soil, at pH 3.5 at 0.36 microequivalents H(+)/hr/g soil, and at pH 4.0 at 0.04 microequivalents H(+)/hr/g soil. Assuming a weathering rate proportional to (H(+)) to the m power, the fractional order m was determined to be approximately 0.8. Results were consistent with a surface reaction-controlled dissolution mechanism. (Author's abstract)

Rainbow trout (Oncorhynchus mykiss, formerly Salmo gairdneri) are sensitive to a number of chemical hepatocarcinogens. This study was conducted to determine whether, in the rainbow trout carcinogenesis model, proliferation of liver cells in response to post-initiation treatment with carbon carcinogenesis model, prolineration of liver cells in response to post-initiation treatment with carbon tetrachloride (CCI4) enhances liver tumor development. Rainbow trout were microinjected at the sac fry stage of development with dimethyl sulfoxide (DMSO; control) or 20 ng aflatoxin B1 (AFBI) in DMSO. Following microinjection, half of the fish were not treated further and the remainder were repeatedly exposed to 1 mL/kg doses of CCl4 by intraperitoneal (i.p.) injection. Examination of sections of liver tissue from trout sacrificed 2 weeks after injection with CCl4 revealed that there ancer injection with CCI4 revealed that there was focal necrosis of hepatocytes and numbers of mitotic figures were elevated throughout the liver. No pathological lesions were seen on any of the internal organs except the liver. Hepatocellular carcinomas were observed at both the 3 and 6 month necropsies in treatments with AFB1 initi-

ation. No grossly-visible liver lesions were observed in the DMSO and DMSO+CCl4 groups at 3 or 6 months. Only single tumors were generally observed grossly in the AFBI group, whereas in the AFBI+CCl4 group, both single and multiple (2 to 4) tumors were observed grossly in the livers. (2 to 4) tumors were observed grossly in the invers. There was no significant difference between AFB1 and AFB1+CCl4 treatments in the total incidence of basophilic lesions (preneoplastic plus neoplastic) observed in the histologic survey. Multiple treatments with CCl4 enhanced AFB1-initiated hepatoments with CCl4 enhanced AFBI-initiated hepato-carcinogenesis in trout over a short latency period (3 months). However, an obvious enhancing effect by multiple treatments with CCl4 over a longer latency period (6 months) was not seen. Exposure of wild fish to weak carcinogens in association with hepatotoxic chemicals or pathogens may lead to liver tumor development. (VerNooy-PTT) W91-11301

TOXICITY OF METALS TO A FRESHWATER TUBIFICID WORM, TUBIFEX TUBIFEX

Industrial Toxicology Research Centre, Lucknow (India). Preventive Toxicology Div.

Bulletin of Environmental Contamination and Toxicology BECTA6, Vol. 46, No. 6, p 906-912, June 1991. 2 tab, 18 ref.

Descriptors: \*Bioindicators, \*Heavy metals, \*Metals, \*Toxicity, \*Toxicology, \*Tubificids, \*Water pollution effects, Aquatic animals, Bioassay, India, Sublethal effects.

The freshwater tubificid worm, Tubifex tubifex (Muller) forms an important link in aquatic food chains and are useful indicators of varying degrees of aquatic pollution. Tubificid worms were collected from the Gheru Campus of ITRC, Lucknow, India, and exposed to concentrations of 33 metal ions in replicates of three. The 24, 48, and 96-hour ions in replicates of three. The 24, 48, and 96-hour EC50s (effective concentration at which 50% immobilization response was recorded) and 95% confidence limits were determined. The metal ions tested included Os, Ag, Pb, Hg, Pt, Pd, Cr, Bi, U, Se, Li, As, Be, Zn, Sn, Mo, La, Ba, Cd, Ni, Al, Fe, Co, Te, Mg, Mn, Zr, Sr, Ca, Sb, Na, and K. Results suggest that osmium (0s) and silver (Ag) were the most toxic (48-hour EC50s were 0.009 and 0.039 mg/L), and sodium (Na) and potassium (K) the least toxic ions (48-hour EC50s were 1016 and 1320 mg/L). Results also suggest that mercury (Hg), copper (Cu) and cadmium (Cd) are more and 1520 mg/L). Results also suggest that increasing (Hg), copper (Cu) and cadmium (Cd) are more toxic than chromium (Cr), zinc (Zn), and nickel (Ni). It is suggested that there is a common, non-specific, toxic action for most metal cations, which specific, toxic action for most metal cations, which can be related to their strength of covalent binding to the ionogenic group, for example, with imidazole, carboxyl and sulphydryl groups. However, for non-transitional metal cations, enzyme inhibition is not likely to be a primary factor in toxicity. But osmotic or other colligative factors operating though physical reactions cause physical damage to the cellular system. (VerNooy-PTT) W91-11303

ASSESSMENT OF MERCURY TOXICITY BY THE CHANGES IN OXYGEN CONSUMPTION AND ION LEVELS IN THE FRESHWATER SNAIL, PILA GLOBOSA, AND THE MUSSEL, LAMELLIDENS MARGINALIS.

Sri Krishnadevaraya Univ., Anantapur (India). Dept. of Zoology.

B. Sivaramakrishna, K. Radhakrishnaiah, and A.

Bulletin of Environmental Contamination and Toxicology BECTA6, Vol. 46, No. 6, p 913-920, June 1991. 5 fig, 16 ref.

Descriptors: \*Heavy metals, \*Mercury, \*Mussels, \*Snails, \*Toxicity, \*Toxicology, \*Water pollution effects, Animal metabolism, Animal tissues, Bioassay, Bivalves, Gastropods, Median tolerance limit, Mortality, Sublethal effects, Tissue analysis.

The concentration of mercury (Hg) in aquatic ecosystems has been significantly increasing with the discharge of the effluents from various industries. The level of tolerance of the freshwater gastropod

### Group 5C-Effects Of Pollution

Pila globosa (Swainson) and of freshwater bivalve Lamellidens marginalis (Lamarck) to mercury at lethal and sublethal levels was determined and compared with the rate of whole animal oxygen consumption and the level of sodium, potassium consumption and the level of sodium, potassium and calcium ions in the hepatopancreas and the foot of these animals. The 120 hour LC50s for snails obtained from percent and probit mortality curves and Dregstedt and Behren's method are 4.467, 4.467 and 4.477 mg/L, respectively, and for mussels 3.311, 3.020 and 2.754 mg/L. The high tolerance capacity of snails and mussels to mercury could be due to their sedentary nature and/or adaptive ability, or because these animals may close up and not react to their environment. The rate of oxygen consumption of snails and mussels decreased at the respective exposure periods studdecreased at the respective exposure periods studdecreased at the respective exposure periods stud-ied in both lethal and sublethal concentrations of mercury. Data revealed a decrease in sodium, potassium and calcium levels in hepatopancreas and an increase in sodium levels in the foot of snails and mussels exposed to mercury. In lethal concentrations there was a gradual net loss of these ions from 1 to 5 days. In sublethal concentrations, the slow regain of the sodium, potassium and calcium ions and the gradual recovery in the rate of oxygen consumption to normalcy indicate the attainment of homeostasis on prolonged exposure of these animals to chronic toxic stress. These compensatory adjustments were more or less similar in both animal groups (VerNooy-PTT)

Descriptors: \*Environmental impact, \*Fungi, \*Litter, \*Mine wastes, \*Water pollution effects, Coal mine wastes, Coal mining effects, Decomposition, Leaves, Water pollution sources.

Although fungi play an important role in the func-Atthough using just an important role in the func-tioning of many freshwater systems, information on their response to pollutants is scarce. The aim of this study was to investigate the effect of coal-mine effluent on the structure and functioning of fungal assemblages. Fungi present above and below the effluent outfall of a disused coal mine below the effluent outfail of a disused coal mine were surveyed. In the upstream site there were more species (23 compared to 20) and, possibly more importantly, twice as many aquatic Deuteromycotina. It is this group of fungi, which includes the aquatic Hyphomycetes, that has been implicated in leaf litter breakdown, and litter-bag experiments confirmed that decomposition rates were reduced below the effluent outfall. In addition reduced below the effluent outfall. In addition, leaves incubated at the downstream site had higher C:N ratios. Results from this study suggest that the mine effluent was having an effect on: the fungi present, the rate of leaf breakdown, and the biochemical composition of decomposing leaves. The chemical composition of decomposing leaves. The implications of these effects for invertebrate shredders are considerable. (Author's abstract) W91-11320

The explosive demographic growth in Latin America and the Caribbean over the past years, with the increased demand for water resources, has accelerated the construction of multipurpose reservoirs for potable and industrial water supplies, irrigation water and hydroelectric power. Many of these reservoirs and also natural lakes have suffered the effects of eutrophication which has inter-fered with the designated uses of these water bodies, and as such, the very purposes for which the reservoirs were created. The Pan American Center for Sanitary Engineering and Environmen-tal Sciences (CEPIS), a specialized Center of the Pan American Health Organization/World Health Organization (PAHO/WHO), has conducted a Re-gional Program since 1981 for the development of simplified methodologies for the evaluation of eu-trophication in warm-water tropical lakes/reservoirs of Latin America and the Caribbean. The majority of the regional lakes/reservoirs appear to majority of the regional lakes/reservoirs appear to be phosphorus limited. A warm-water tropical lake trophic state classification system and a simplified total phosphorus model have been developed with regional data, and successfully verified against the data of other lakes/reservoirs of the African continent. The use of the phosphorus model as a predictive tool in the management and planning of water resources is of more than scientific interest, since the desired water uses are closely dependent on the desired water uses are closely dependent on trophic state and consequent water quality. Given a total phosphorus concentration and using the model, the percent probability of the trophic state of a warm water tropical lake/reservoir can be determined. (Doyle-PTT) W91-11332

RESULTS OF THE FIRST PILOT-SCALE CONTROLLED COHORT EPIDEMIOLOGICAL IN-VESTIGATION INTO THE POSSIBLE HEALTH EFFECTS OF BATHING IN SEA-WATER AT LANGLAND BAY, SWANSEA. F. Jones, D. Kay, R. Stanwell-Smith, and M. Wyer.

Wyer. Journal of the Institution of Water and Environ-mental Management JIWMEZ, Vol. 5, No. 1, p 91-98, February 1991. 8 tab, 45 ref.

Descriptors: \*England, \*Epidemiology, \*Public health, \*Swimming, \*Water pollution effects, \*Water quality standards, Beach contamination, Comparison studies.

A pilot study was conducted to investigate the feasibility of using adult volunteers to examine the possible health effects of bathing in England's seawaters which passed the European Community (EC) bathing waters Directive. Adult volunteers were recruited from the City of Swansea and ranwere recruited from the City of swanses and ran-domly divided into bather and non-bather groups. All volunteers were given medical examinations and medical questionnaire interviews before and after the bathers were required to swim in the sea and immerse their heads underwater at least three times during bathing. Non-bathers were required to visit the designated beach area on the same day as the bathers but were not permitted to enter the water. Water quality on the day of bathing was relatively unpolluted as indexed by bacterial and viral indicator species. The detailed medical ques-tionnaire resulted in higher reported attack rates of perceived illness in both bather and non-bather groups than those published in previous studies,

which have commonly employed a single tele-phone interview to acquire disease perception data. Statistically-significant differences in the batter and non-bather cohorts were found for the followand non-bather cohorts were found for the following perceived symptoms: sore throat, ear symptoms, eye symptoms at 3 days after swimming, and
diarrhea at three weeks after swimming. The clinical tests employed failed to confirm these significant perceived symptom attack rate differentials.
This novel prospective controlled cohort approach, if taken to a full-scale study, could offer
considerable advantages over nast methods of colconsiderable advantages over past methods of col-lecting health effect data of recreational water use, such as retrospective studies, prospective percep-tion studies, or cross-sectional investigations. (Geiger-PTT) W91-11366

DOWNSTREAM CHANGES IN CADDISFLY COMPOSITION AND ABUNDANCE IN RELA-TION TO CHANGES IN WATER CONDUCTIV-ITY AND OXYGEN IN THE RIVER BUTRON ASTN.

Universidad del Pais Vasco, Bilbao (Spain). Lab. de Ecologia.

A. Basaguren, and E. Orive. Internationale Revue der Gesamten Hydrobiologie IGHYAZ, Vol. 75, No. 3, p 303-316, 1990. 4 fig, 3 tab, 30 ref.

Spain, Species composition.

The Butron River in the Basque Country (northern Spain) is a low gradient watercourse with a bottom of gravel and sand for most of its length surrounded by clear-cut areas of conifer plantations. Changes in the structure, abundance, and distribution of caddisfly larvae along the main courses of the river basin in relation to selected physicochemical variables were studied. Samples were obtained during all four seasons of the year on twenty-one sites in the main river and its tributaries. Species diversity was measured using the Shannon-Weaver index. Four main areas were identified in the river basin based on trichopteran taxa: (1) small intermittent streams and the first site of the main river, (2) the higher parts of small af-fluents, (3) the permanent upper part of the main river together with the lower site of a small tribu-tary drawing to this river at its upper part, and (4) there together with the lower site of a small ributary draining to this river at its upper part, and (4) the middle and lower parts of the main river as well as small tributaries entering this river in its lower part. Area 1 was characterized by individuals of Rhyncophila eatoni, Plectrocnemia conuals of Rhyncophila eatoni, Plectrocnemia con-spersa and P. geniculata. Areas 2 and 3 had a relatively rich and diverse assemblage of different species of Rhyncophila, Hydroptila, Hydropsyche, Polycentropus flavomaculatus and Athripsodes braueri. Area 4 had hydropsychid larvae, mainly H. bulbifera and H. lobata which were predomi-nant downstream. Differences in trichopteran as-semblage structure were related to water flow, oxygen content of the water and increasing down-stream mineralization which indicated increasing pollution. (Medina-PTT)

ASSESSMENT OF WATER POLLUTION USING DIATOM COMMUNITY STRUCTURE AND SPECIES DISTRIBUTION—A CASE STUDY IN A TROPICAL RIVER BASIN.

Biological assessment of water pollution using diatom community structure and species distribu-

### Effects Of Pollution—Group 5C

tion was carried out in the Linggi River Basin, Malaysia which is polluted by various urban, industrial and agricultural wastes. A total of 86 diatom taxa belonging to 21 genera were recorded, from eight sampling stations located in the basin, of which is a property of the sample of the basin, of which is a property of the sample of the basin, of which is a property of the sample of the basin, of which is a property of the sample of which 70 species were found on artificial sub-strates; the remaining 16 species were recorded exclusively on natural substrates. The number of diatom species observed between the stations varied from 22-47 species. The dominant diatom varied from 22-47 species. The dominant diatom species in decreasing order of abundance were Eunotia vanheurckii, Nitzschia palea, Achnanthes minutissima. Gomphonema parvulum and Achnanthes minutissima. The most common clean water species were A. minutissima. A. linearis and Synedra rumpens. The most tolerant species were N. palea, followed by G. parvulum and Pinnularia braunii. E. vanheurckii and Navicula cryptocephala occurred in high densities at both unpolluted and product of the product of t polluted stations and were considered to be the common facultative or indifferent species. Al-though a large number of species were recorded at the unpolluted stations, an equivalent number of species were also found at the moderately polluted stations. However, the number of species was markedly reduced at grossly polluted stations. However, even though there was a marked variation in species association between the unpolluted and polluted stations, there was no such association among the polluted stations to distinguish the type and degree of pollution. USEFULNESS OF VARIOUS NUMERICAL METHODS FOR ASSESSING THE SPECIFIC EFFECTS OF POLLUTION ON AQUATIC

EFFECTS OF PULLUTION OF ACCOUNTS OF THE STATE OF T

Descriptors: \*Aquatic life, \*Pollution index, \*Statistical methods, \*Water pollution effects, Cluster analysis, Comparison studies, Data interpretation, Ecosystems, Germany, Mathematical analysis, Performance evaluation, Species composition, Statistical analysis, Performance evaluation, Pe

An extensive multidisciplinary study of a polluted harbor basin in Hamburg, Germany, was conducted using various methods to determine which staharbor basin in Hamburg, Germany, was conducted using various methods to determine which statistical methods are easiest to interpret and permit the most accurate evaluations. The methods analyzed include the species deficit, index of species similarity, saprobity index, and the more complex cluster and gradient analyses (which revealed a variety of relationships among the biotic communities at the various sampling sites and some ecological tolerance limits of various species). Some contradictory results were obtained using the simpler indices because species deficit takes no cognizance of the identities of the species encountered, while the index of species similarity does. Large discrepancies among the saprobity indices indicated that this index provides a basis for rough comparison with inaccurate characterization of water conditions due mainly to the occasional abundance of obiquitous species with broad tolerances that have been assigned arbitrary saprobity values. The cluster and gradient analyses revealed a variety of relationships among the biotic communities at the various sampling sites along with some ecological tolerance limits of various species. The results reveal the qualitative effects of influx of species from the Elbe and from the storm drains of Hamburg and confirm the destructiveness of organic nollutants which spread their effects seasonally from the Eule and from the storm drains of Hain-burg and confirm the destructiveness of organic pollutants which spread their effects seasonally from one part of the harbor. While it is evident that no one statistical method or index adequately that no one statistical method or index adequately represents the highly complex ecological condi-tions in a water body, using a variety of such methods to analyze sampling data provides many valuable insights into the processes taking place in the system. Resource managers need to predict effects of pollution episodes on aquatic biota, and suspended sediment is an important variable in considerations of freshwater quality. Despite considerable research, there is little agreement on environmental effects of suspended sediment as a function of concentration and duration of exposure. More than 70 papers on the effects of inorganic suspended sediments on freshwater and marine fish and other organisms were reviewed to compile a date base. segments on resolvater and marine is and other organisms were reviewed to compile a data base on such effects. Regression analysis indicates that concentration alone is a relatively poor indicator of suspended sediment effects. The product of sediof suspended sediment effects. The product of sedi-ment concentration and duration of exposure is a better indicator of effects. An index of pollution intensity (stress index) is calculated by taking the natural logarithm of the product of concentration and duration. The stress index provides a conven-ient tool for predicting effects for a pollution epi-sode of known intensity. Aquatic biota respond to both the concentration of suspended sediments and duration of exposure much as they do for other duration of exposure, much as they do for other environmental contaminants. Researchers should, therefore, not only report concentration of sus-pended sediment but also duration of exposure of aquatic biota to suspended sediments. (Author's

APPROACHES TO THE SIMULATION OF RE-GIONAL CLIMATE CHANGE: A REVIEW. National Center for Atmospheric Research, Boul-

F. Giorgi, and L. O. Mearns. Reviews of Geophysics RVGPB4, Vol. 29, No. 2, p 191-216, May 1991. 15 fig, 1 tab, 123 ref.

The increasing awareness that enhanced levels of greenhouse gasses of direct or indirect anthropogenic origin might substantially change the climate of different regions of the world has rendered the issue of regional climate simulation critically important. The problem of projecting regional climate changes can be identified as that of representing effects of atmospheric forcings, i.e., forcings which modify the general circulation and determine the sequence of weather events which characterize the climate regime of a given region (for example, greenhouse gas abundance), and mesoscale forcings, i.e., forcings which modify local circulations, thereby regulating the regional distribution of climatic variables (for example complex mountain systems). General circulation models (GCMs) are the main tools available today for (GCMs) are the main tools available today for climate simulation. However, they are run and will likely be run for the next several years at resolu-tions which are too coarse to adequately describe

mesoscale forcings and yield accurate regional climate detail. These approaches can be divided into three broad categories: (1) Purely empirical approaches in which the forcings are not explicitly accounted for, but regional climate scenarios are constructed by using instrumental data records or paleoclimatic analogues; (2) semiempirical approaches, in which GCMs are used to describe the atmospheric response to large-scale forcings of relevance to climate changes, and empirical techniques account for the effect of mesoscale forcings; and (3) modeling approaches, in which mesoscale forcings are described by increasing the model resolution only over areas of interest. Since they are computationally inexpensive, empirical and semiempirical techniques have been more widely used. More recently, a nested GCM-limited area model has been developed with encouraging preliminary results and has a wide range of applications. (Medina-PTT) W91-11427

The impact of a concentrated pulse (16 micrograms/L) of the pyrethroid insecticide permethrin (emulsifiable concentrate) was evaluated on the macroinvertebrate community of a northern Ontario headwater stream. Post-treatment drift increased by a factor of 2,400 within minutes of the arrival of the insection. the insecticide. There was a significant reduction in the abundance of invertebrates in most families as far as 260 m below the point of injection in both kick and artificial substrate samples. Greatest impact was observed in the mayflies Baetis flavistriga, Heptagenia flavescens, and Epeorus sp.; the stonefly Leuctra tenuis; and the caddisfly Dolophiclodes distinctus. Diptera were not significantly reduced. The number of species occurring 100 m from the point of injection was reduced by 47%, but only by 17% at 260 m. There was no change in the percent composition of functional feeding but only by 17% at 200 m. Incre was no change in the percent composition of functional feeding groups at any points after treatment. Recovery of most invertebrates was complete within 6 weeks of treatment. However, under of repeated exposures, as might be required for severe infestations by defoliating pests, the potential for long-term change in taxonomic and functional structure of a cnange in taxonomic and functional structure of a stream increases. The problem could be exacerbat-ed by the spraying of wide tracts of forests such that neighboring streams, also affected, could not provide a source of aerial recolonization for recov-ery of directly affected stream. ### **Group 5C—Effects Of Pollution**

Distilled water, Formaldehyde, India, Ketones, Loam, Mercury, Nickel, Sandy soils, Soil types, Thin layer chromatography, Zinc.

Thin layer chromatography was used to investi-gate the effect of organic pollutants such as alco-hols, ketones, and aldehydes on the mobility of heavy metals in an acidic sandy loam soil from neavy metais in an acidic sandy loam soil from Orissa (India). The mobility of metal ions (measured in R sub f units) was observed to increase in accordance with their decreasing radii except in the case of mercury. The addition of 5% alcohols in the developer (distilled water) increased the mobility of cobalt, nickel, zinc, and cadmium (except Cd in ethanol) while it decreased copper (except Cd in ethanol) while it decreased copper and mercury mobility (except copper in propanolamended developer). In a 5% formaldehyde water system, the mobility of all heavy metals studied increased significantly, except in the case of copper and mercury. In the acetaldehyde system, heavy metal mobility followed the formaldehyde pattern with 5% acetaldehyde. In the 5% benzaldehyde water system, the mobility of Cu, Hg, Co, and Cd decreased to about 0.1 R sub f units (mean) and then increased but remained lower than the condecreased to about 0.1 K sub 1 units (mean) and then increased, but remained lower than the control (distilled water). Acetone and ethyl methyl ketone decreased the mobility of Hg, Cu, and Cd, while cyclohexanone decreased Hg mobility by 0.07 and increased that of Cu and Cd by 0.03 and 0.04 R sub 1 units respectively. The mobility of 0.07 and increased that of Cu and Cd by 0.03 and 0.04 R sub f units, respectively. The mobility of Co, Ni, and Zn increased significantly in all ketone water systems. It is concluded that the blockage of soil adsorption sites by organic pollutants appears to enhance the mobility of heavy metals except in some cases at lower concentrations. (Doria-PTT) W91-11457

EFFECTS OF CHLORNITROFEN, A HERBI-CIDE, ON REPRODUCTION OF BRA-CHIONUS URCEOLARIS (ROTATORIA) THROUGH WATER AND FOOD (CHLOREL-

National Inst. for Environmental Studies, Ibaraki (Japan). Environmental Biology Div.

S. Hatakeyama.
Environmental Pollution ENPOEK, Vol. 70, No. 2, p 143-156, 1991. 3 fig, 3 tab, 33 ref.

Descriptors: \*Chlornitrofen, \*Herbicides, \*Pesticide toxicity, \*Reproduction, \*Water pollution effects, Algae, Chlorella, Eggs, Growth, Growth stages, Invertebrates, Lethal limit, Survival.

Chronic effects of chlornitrofen (CNP) on the reproduction of Brachionus urceolaris (Rotatoria) were investigated by exposure of individuals to CNP from the egg stage, which had been attached to the adult. The survivors of 12 neonates exposed to CNP (100, 70, or 40 micrograms/L) decreased to 50% at ages of 2, 4, and 6 days, respectively, compared to 6.5 days for those exposed to 1, 20, and 20 micrograms/L. Release of offspring (mostly 2 individuals/day) started at an age of 2 days. At the peak (4 d), a control female produced 8.1 offspring/d compared with 4.5 at 40 micrograms/L. The cumulative numbers of offspring produced by a female were 25.8, 24.2, 22.3, and 13.6 at control, 10, 20, and 40 micrograms/L, and 13.6 at control, 10, 20, and 40 micrograms/L, respectively. The 50% reproductive impairment concentration was calculated to be 37 micrograms/L. Growth of neonates was barely detectable at 70 micrograms/L, and the rapid increase in the effect of CNP from 40 to 70 micrograms/L was attributed to an increase in tolerance with growth of the neonates. The effects of CNP on reproduction were tested by CNP exposure through food (CNP-accumulated Chlorella). The 50% reproductive impairment concentration of CNP in the alga was calculated to be 600 micrograms/g (wet weight) by the same method used to assess the dissolved CNP, although the effect of CNP that may have been released from the alga to the water could not be estimated precisely. Descriptors: \*Environmental effects, \*Eutrophica-tion, \*Pulp and paper industry, \*Pulp wastes, \*Water pollution effects, \*Water pollution sources, Biological oxygen demand, Biological treatment, Bleaching wastes, Industrial wastes, Nitrogen, Phosphorus.

During recent years the biological oxygen demand-loading of pulp and paper mill wastewaters has decreased dramatically, due to more effective circulation of water in the processmore effective circulation of water in the process-es, and the new activated sludge biological treat-ment plants. This traditional threat to the environ-ment has been forgotten by the scientists who are currently more concerned with the role of chlorine compounds discharged from bleaching processes. However, eutrophication due to nutrient loading is still present in many recipient waters of pulp and paper industry effluents. The biological oxygen demand reduction has often been carried out at the cost of adding nutrients, phosphorus and nitrogen, to the purification processes. Biological treatment has decreased the inhibitive effect of wastewater on the biological production of the recipient water body, thus causing eutrophication to arise immedi-ately. There has been a remarkable and extensive ately. There has been a remarkable and extensive development in the prevention of eutrophication of pulp and paper wastewater recipient water bodies. Treatment has been carried out effectively, from suspended solids to oxygen demand, to the decrease in phosphorus loading and management of collorinated compounds. Eutrophication remains, however, a very real problem. (See also W91-11467) (Mertz-PTT) W91-11509

Chanomi Creek, an estuarine system in the lower Niger delta of Nigeria, was evaluated between December 1984 and April 1985, to ascertain how far the system had recovered approximately three far the system had recovered approximately three years after some areas had been damaged by a crude oil spill. Hydrobiological indices had ranges of: pH, 6.8 to 8.1; depth, from 2.65 m to > 15 m; temperature, 24 C to 29 C; transparency, 0.75-1.75 m; alkalinity, 1.10-1.53 microeq/L; total dissolved solids, 11.1-32.0 mg/L; dissolved oxygen, 7-13 mg O2/L; percentage oxygen saturation, 94% to 6.65 solids, 11.1-32.0 mg/L; dissolved oxygen, 7-13 mg O2/L; percentage oxygen saturation, 94% to 155%; and a 24-hr biological oxygen demand (25 c), 0.17-3.66 mg O2/L; mean chlorophyll a, 3.55 mg/cu m to 9.43 mg/cu m; and, gross phytoplankton productivity, 40-813 mg O2/L/h. Phytoplankton consisted predominantly of diatoms (over 41 species), followed by dinoflagellates (7 species). Zooplankton density was high (42,877-527,708 organisms/10 min, 5 knot/h tow), with populations of adult calanoid and cylcopoid copepods, copepod nauplii, barnacle nauplii, larvaceans, and larvae of polychaetes, gastropods, and shrimp. There is some evidence that Chanomi Creek has recovered from the 1982 oil spill. (Doria-PTT)

RISE AND FALL OF THE POTOMAC RIVER STRIPED BASS STOCK: A HYPOTHESIS OF THE ROLE OF SEWAGE.

Maryland Univ., Solomons. Chesapeake Biological

C. Tsai, M. Wiley, and A. Chai.

Transactions of the American Fisheries Society TAFSAI, Vol. 120, No. 1, p 1-22, January 1991. 16 fig, 1 tab, 86 ref.

Descriptors: \*Bass, \*Estuarine fisheries, \*Fish populations, \*Potomac Estuary, \*Spawning, \*Wastewater facilities, \*Wastewater pollution, ontrol, \*Water pollution control, \*Water pollution effects, Biological oxygen demand, Fertility, Fish larvae, Growth stages, Model studies, Nutrients, Phytoplankton, Zooplankton.

The spawning and nursery area of striped bass Morone saxatilis in the Potomac River is located about 30 km downstream from the outfall of the Blue Plains sewage treatment plant in Washington, D. C. The area coincides with the fertile zone of the river that receives sewage from several treat-ment plants and has abundant phytoplankton and zooplankton. During the striped bass spawning season, April to June, there is a longitudinal downseason, April to June, there is a longitudinal down-river succession of sewage nutrients, phytoplank-ton, zooplankton, and striped bass larvae, suggest-ing the presence of a trophic link between sewage nutrients and larvae. A transfer function-noise model of average daily biological oxygen demand loadings from sewage treatment plants and the total commercial landings of striped bass from 1938 to 1983 was developed. The model suggests a causal relationship between the sewage nutrients and the fishery. A multiplicative decomposition and the fishery. A multiplicative decomposition analysis of striped bass juvenile indices from 1958 to 1986 suggests that sewage nutrients play an important role in recruitment. It is hypothesized that an increase in sewage raised the fertility of the spawning and nursery regions and was responsible for the abundance of striped bass from the 1940s through the 1960s. It is further hypothesized that improvements in sewage treatment processes since the early 1970s have greatly lowered sewage nutri-ent loading, lowered fertility in the spawning and nursery regions, and contributed to the recent de-cline of striped bass in the Potomac Estuary. CHEMICAL AND BIOLOGICAL FACTORS AFFECTING ACID TOLERANCE OF SMALL-MOUTH BASS.

Ontario Ministry of Natural Resources, Maple. Fisheries Branch

B. J. Shuter, and P. E. Ihssen.

Transactions of the American Fisheries Society TAFSAI, Vol. 120, No. 1, p 23-33, January 1991. 3 fig, 4 tab, 15 ref.

Descriptors: "Acid rain effects, "Acidity, "Bass, "Fish physiology, "Laboratory methods, "Water pollution effects, Calcium, Experimental design, Fish, Growth stages, Hydrogen ion concentration, Snowmelt, Sodium, Survival, Temperature.

The effects of starvation on acid tolerance of young-of-year smallmouth Micropterus dolomieui were investigated in the laboratory. Juvenile smallmouth bass, held under simulated winter conditions for up to 5 months, experienced losses in ashfree dry weight of up to 30%. However, consecutive tests failed to demonstrate any decline in the short-term (up to 7 d) tolerance of these fish for pH levels in the range from 3.0 to 4.5. Results confirm that hypersensitivity to short-term, very low pH exposure is of no significance under conditions (winter duration, temperature, fish size) typicals. low pit exposure is or no significance under condi-tions (winter duration, temperature, fish size) typi-cal of populations in south-central Ontario. The duration of the winter starvation period typically experienced by such populations is too short to affect their ability to withstand the severe, short-term pH depressions that often accompany spring snowmelt. Calcium and sodium concentration of the water and fish body size (fork length) were all positively related to acid tolerance. A doubling of

### Effects Of Pollution—Group 5C

fork length increased survival time at any pH by 100%. At pH 3.0, a doubling of calcium concentration increased survival time by 13% and at pH 4.0 it increased survival time by 50%. Over the pH range 3.75 to 4.0, doubling sodium concentration increased survival time by 8%. The effect of body size on acid tolerance should be recognized and controlled in future experiments and when laboratory tolerance estimates are used to assess the susceptibility of wild populations to acid stress. Descriptors: \*Acid rain effects, \*Aluminum, \*En-Accomptors: "Actor ram effects, "Aluminum, "Endangered species, "Trout, "Water pollution effects, Acidity, Arkansas River, Colorado, Embryonic growth stage, Fish, Fish eggs, Growth stages, Hydrogen ion concentration, Larval growth stage, South Platte River, Survival.

The greenback cutthroat trout Oncorhynchus clarki stomias is a threatened subspecies native to the upper South Platte and Arkansas rivers between Denver and Fort Collins, Colorado, an area also susceptible to acid deposition. In laboratory studies, this subspecies was exposed to nominal pHs of 4.5-6.5 and to nominal aluminum concentrapris of 4.3-0.3 and to infilm a dufiniting contents of the control was pH 6.5 treatment without Al. Soft water was used that contained 1.3 mg Ca/L. Exposures of 7 d each were made for four early life stages: fertilized egg, eyed embryo, alevin, and swim-up larva. Effects were measured at the end swim-up larva. Effects were measured at the end of exposure and again after a recovery period lasting until 40 d posthatch. The alevin stage was the most sensitive: at pH 5.0 with no Al, survival was reduced by 68% and swimming duration by 76%; at pH 6.0 and 50 micrograms Al/L, swimming duration was reduced by 62%, but survival was not affected. Reductions in whole-body conwas not affected. Reductions in whole-body concentrations of Na, K, and Ca indicated organism stress. Sodium was reduced most: about 50% in alevins exposed to pH 5.0 without Al and to pH 6.0 with 50 micrograms Al/L. Growth and the ratio of RNA to DNA were not affected by any exposure. All responses that were affected during exposure returned to normal by 40 d posthatch. Overall, it appeared that pH 6.0 and 50 micrograms Al/L might be detrimental to greenback cutthroat trout populations. (Author's abstract) W91-11531

Virginia Journal of Science VJSCAI, Vol. 42, No. 1, p 113-122, Spring 1991. 5 fig, 17 ref.

Descriptors: \*Denitrification, \*Elizabeth River, \*Sediment chemistry, \*Sediment contamination, \*Water pollution effects, Algal blooms, Dissolved oxygen, Nitrates, Phytoplankton, Seasonal variation, Temperature, Virginia.

Sediment denitrification potential from two sites in Sediment dentrinication potential from two sites in the Elizabeth River estuary was studied over a 9-month period using the acetylene blockage method. Rates of microbial processes in this envi-ronment are of interest because of the high concentration of toxics present in some parts of the system. Highest rates were found in the highly polluted Southern Branch of the Elizabeth River with nitrate-amended sediment ranging from 2 to 262 nmol N2O/h/20 ml of sediment and exhibiting maximal rates during spring and fall. Rates in the Main Stem of the Elizabeth River are lower, with

less than 1-85 nmol N2O/h/20 ml in nitrate-amendless than 1-85 nmol N2O/h/20 ml in nitrate-amended sediment, and maxima in late fall. Unamended sediment denitrified only minimally in the spring. Sediment denitrification potential was independent of temperature and dissolved oxygen in the water column. Comparison of phytoplankton abundance values and potential denitrification protential may be stimulated by phytoplankton bloom senescence. Comparison to other published studies shows sediment denitrification potential in the Elizabeth River to be within tion potential in the Elizabeth River to be within the range of values reported for other environ-ments. Denitrification potential in the sediments is, therefore, maintained in the presence of toxics in the sediment. (Author's abstra W91-11537

INTERPRETATION OF HYDROLOGIC EF-FECTS OF CLIMATE CHANGE IN THE SAC-RAMENTO-SAN JOAQUIN RIVER BASIN,

Washington Univ., Seattle. Dept. of Civil Engineering.

D. P. Lettenmaier, T. Y. Gan, and D. R. Dawdy. Available from the National Technical Information Service, Springfield, VA. 22161, as PB90-136987. Price codes: A06 in paper copy, A01 in microfiche. Report No. Water Resources Ser/TR-110, June 1988. 11p, 13 fig, 15 tab, 19 ref, 3 append.

Descriptors: \*Global warming, \*Hydrologic budget, \*Climate effects, \*Sacramento River Basin, \*San Joaquin River Basin, \*Model studies, California, Snow, Ablation, Runoff, Simulation analysis, Snowmett, Seasonal variation, Data inter-pretation, Temperature, Precipitation.

Climatic changes were studied in four catchments with areas ranging from 203 to 358 sq mi, in the headwaters of the Sacramento-San Joaquin Basin. Three of the study catchments, The McCloud River, the North Fork American River, and Thomas Creek, lie in the Sacramento River Basin; one, the Merced River, is in the San Joaquin basin. Snow accumulation and ablation, and runoff were simulated under current (and historical) conditions simulated under current (an instorical) conditions using the National Weather Service snowmelt and soil moisture accounting models. The snowmelt model operated on a six hourly time step, while the soil moisture accounting model operated on a daily time step. Once the models were calibrated to present conditions, simulations were performed under seven alternative climate scenarios. All simunder seven aiternative climate scenarios. All similations were performed using 100 yrs of daily temperature and precipitation data (disaggregated to a six hourly interval for the snowmelt model) consisting of the years 1951-80 supplemented by 70 additional years drawn at random from the 1951-80 record. All of the initial scenarios (based on steady state CO2 doubling, or a transient from present conditions to CO2 doubling) showed that the simulated hydrologic changes were dominated by a shift in the snow accumulation pattern. For all but the highest catchment (the Merced), this resulted the highest catchment (the Merced), this resuited in a change from a snow-dominated to a rainfall-dominated hydrologic regime. Long-term runoff was shifted from the spring to the winter. Spring and summer mean runoffs were greatly reduced. In addition, the soil moisture in the winter months increased, and decreased in the spring and summer. increased, and decreased in the spring and summer. Because of the evaporation in the spring, there was a shift in maximum evapotranspiration earlier in the season. These general shifts were observed for all of the alternative climates. They were most severe for the Geophysical Fluid Dynamics Laboratory (GFDL) and Goddard Institute for Space Studies (GISS) CO2 doubling scenarios, for which the temperature shifts were the greatest, and were least severe for the Oregon State University (OSU) model CO2 doubling, for which the predicted temperature increases were < 1/2 those for the GISS and GFDL models for most months. MECHANISMS OF RESISTANCE TO POLY-CHLORINATED BIPHENYLS (PCB) IN TWO SPECIES OF MARINE DIATOMS.

State Univ. of New York at Stony Brook. Marine Sciences Research Center.

M. K. Cohen, A. S. West, E. M. Cosper, and C. F.

Journal of the Marine Biological Association of the United Kingdom JMBAAK, Vol. 71, No. 2, p 247-263, May 1991. 7 fig, 3 tab, 39 ref.

Descriptors: \*Water pollution effects, \*Microbiological studies, \*Polychlorinated \*Marine environment, \*Diatoms, \*Resistance, \*Hudson River estuary, Physiological ecology, Lipids, Bioaccumulation, Food chains.

Clones of Ditylum brightwellii and Thalassiosira nordenskioldii were isolated from New York coastal waters, and PCB-resistance in D. brightwellii was induced in the laboratory by exposure to increasing concentrations of PCB. Resistance could not be similarly induced in T. nordenskioldii but was segrediptiously discovered in unexposure of the property of the proper kioldii, but was serendipitously discovered in unex-posed cultures that had undergone sexual repro-duction. Cells of the resistant strain were substantally larger than those of the sensitivity strain in both species. Larger vacuole space seemed to account for this in D. bright wellij, but in T. nordensitoldij, larger cells contained more carbon. Experiments with 14-C-PCB tracer indicated that PCB accumulation was less in resistant strains of both species. Neutral lipid content/cell, as determined species. Neutral lipid collection. Veil, as determined using the fluorophore Nile Red, was similar for resistant and sensitive strains of both species. Subcellularr examination of lipid droplets in D. brightwellii suggested that the PCB-resistant strain brightwelli suggested that the PCB-resistant strain may be sequestering this lipophilic toxicant in a location removed from physiological activity. In T. nordenskioldii a decreased ratio of neutral lipid:carbon may reduce intracellular accumulation of PCB. These diatom species have developed PCB resistance in the highly PCB-polluted Hudson River estuary and, since they are the preferred food of dominant copepods, they may offer less PCB per unit ration to zooplankton grazers. ASSESSING THE RESPONSE OF EMERALD LAKE, AN ALPINE WATERSHED IN SEQUOIA NATIONAL PARK, CALIFORNIA, TO ACIDIFICATION DURING SNOWMELT BUSING A SIMPLE HYDROCHEMICAL

Geological Survey, Doraville, GA. Water Res Div.

R. P. Hooper, C. T. West, and N. E. Peters. Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 90-4000, 1990. 68p, 10 fig, 4 tab, 27 ref, 2 append.

Descriptors: \*Acid rain, \*Acidification, \*Emerald Lake, \*Lake acidification, \*Model studies, \*Snow-melt, \*Water chemistry, \*Water pollution effects, California, Computer programs, Sulfates, Weather-

A sparsely parameterized hydrochemical model has been developed by using data from Emerald Lake watershed, which is a 120-ha alpine catch-Lake watershed, which is a 120-ha alpine catchment in Sequoia National Park, California. Greater than 90% of the precipitation to this watershed is snow; hence, snowmelt is the dominant hydrologic event. A model which uses a single alkalinity-generating mechanism, primary mineral weathering, was able to capture the pattern of solute concentrations in surface waters during snowmellt. An empirical representation of the weathering reaction, which is based on rock weathering stoichimetry and which uses discharge as a measure of action, which is based on rock weathering stoichi-ometry and which uses discharge as a measure of residence time, was included in the model. Results of the model indicate that current deposition levels would have to be increased between three-fold and eight-fold to exhaust the alkalinity of the lake during snowmelt if there is a mild acidic pulse in the stream at the beginning of snowmelt as was observed during the study period. The acidic pulse in the inflow stream at the onset of snowmelt was less pronounced than acidic pulses observed in the

### **Group 5C—Effects Of Pollution**

meltwater draining the snowpack at a point using snow lysimeters or in the laboratory. Sulfate con-centrations in the stream water were the most constant: chloride and nitrate concentrations inconstant; circular and initiate concentrations in-creased slightly at the beginning of snowmelt. Ad-ditional field work is required to resolve whether an acidic meltwater pulse occurs over a large area an action mentwater puise occurs over a large area as well as at a point (implying sulfate-regulating mechanisms in the soil) or whether, due to physical and chemical processes within the snowpack, the acidic meltwater pulse is attenuated at the catchment scale. The modest data requirements of the model permit its applications to other alpine water-sheds that are much less intensively studied than Emerald Lake watershed. (Author's abstract)

### 5D. Waste Treatment Processes

BOSTON'S SEWAGE OUTFALL.

D. T. Palmer.

Civil Engineering (ASCE) CEWRA9, Vol. 61, No. 4, p 74-76, April 1991. 2 fig.

It took centuries of neglect to make Boston Harbor the nation's dirtiest. Now the city has nine years to the nation's dirtiest. Now the city has nine years to clean up. The Deer Island wastewater treatment plant will be the centerpiece of the \$6 billion cleanup effort. Making the plant effective and completing the project on time means fast-tracking the design and geotechnical work, and boring a 10 mile outfall tunnel at record speed. Presently, undersized and outdated plants on Deer and Nut islands provide minimal treatment to Boston area sewage. Two cross-harbor tunnels carry samples provide minimal treatment to boston area sewage. Two cross-harbor tunnels carry wastewater to the existing Deer Island plant. When the new plant is built, sewage that presently goes to the Nut Island plant will bypass it and flow across the harbor through a new tunnel, 12 feet in across the harbor through a new tunnel, 12 feet in diameter. Together, the three tunnels and the new plant will serve 43 municipalities. The Deer Island facility's peak capacity of 1270 million gallons/day will make it the second largest in the U.S. In order to meet the court-mandated deadlines, the tunnel boring machine will have to set a record pace. Tunneling and offshore drilling are both high-risk work; this project will mix the two when the tunnel is being connected to its risers. Three safety barriers will be used in the connection area: water tight caps on the diffuser nozzles; a plug in each riser, to be removed only after the breakthrough from the tunnel is made and checks for leaks have been carried out; and a bulkhead in each riser offtake. All barriers will be removed at various stages of constructions or that the outfall can function. After the tunnel is completed it will be filled tion. After the tunnel is completed it will be filled from the shaft end with clean, chlorinated seawater from the snart end with clean, chlorinated seawater to prevent biofouling. When the tunnel risers are full, crews will remove port caps. The treated effluent will then be diverted to the shaft, purging the outfall of seawater before discharging into the bay. MEASURES FOR PURIFICATION OF THE LEACHATE FROM 'RENSEANLAEG DAMHU-SAEN' INTO COPENHAGEN WATERS, TO MEET THE NPO-PLAN.

Danmarks Ingenioerakademi, Lyngby. Kemiafde-

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 703-706, 1991. 3 fig, 2 tab, 8 ref.

Descriptors: \*Copenhagen, \*Denmark, \*Lea-chates, \*Marine environment, \*Wastewater treat-ment, \*Water pollution control, \*Water pollution ment, "water politution control," water politution treatment, Biological wastewater treatment, Environmental protection, Nitrogen removal, Ocean dumping, Organic matter, Phosphorus removal, Wastewater disposal.

Measures to reduce the leaching of organic material and nitrogen compounds from the land area at 'Renseanlaeg Damhusaen' sewage plant were compared. The Danish NPO-Plan of 1987, designed to protect the marine environment, has the following goals: (1) all waste water should be treated to remove organics, nitrogen and phosphorus, before discharge to the ocean; and (2) nitrogen loads on the ocean from Denmark should be reduced by 50% and the phosphorus loads by 80%. Suggested measures are either total leachate collection followed by biological treatment or selected leachate collection and treatment, followed by distribution of 'high-N' water for domestic use other than drinking. The latter solution will, if generally used, protect groundwater resources as well as marine life. (Brunone-PTT) W91-10601

STUDY OF CAMPYLOBACTER IN SEWAGE. SEWAGE SLUDGE AND IN RIVER WATER. Forschungsinstitut fuer Mikrobiologie und Hygiene, Bad Elster (German D.R.). W. Stelzer, and J. Jacob.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 117-120, 1991. 4 tab, 7 ref.

Descriptors: \*Bacterial analysis, \*Campylobacter, \*Germany, \*Path of pollutants, \*River systems, \*Sludge, \*Wastewater, \*Water analysis, \*Water pollution sources, Agars, Culture media, Culturing techniques, Digested sludge, Electrophoresis, Farm wastes, Feces, Oxidation ponds, Poultry, Survival, Temperature effects, Water quality, Waterfowl.

The occurrence of campylobacters was determined Ine occurrence of campylobacters was determined in wastewater and sewage sludge and in the river system Weisse Elster (Germany). The selective medium used consisted of blood agar supplemented with the antibiotics vancomycin, cephalexin, trimethoprim, polymycin B, and rifampicin. Raw sewage samples contained about 1,000 Campylobacter/100 ml, while the effluent showed an average statistics of 130/1001 and Provinces. bacter/100 ml, while the effluent showed an aver-age concentration of 130/100 ml. Raw sewage from an oxidation pond contained an average of 51 Campylobacter/100 ml, while none were found in the effluent. No Campylobacter could be found in digested, conditioned studge. The organism could be detected in 82.1% of river waters examined, with the majority showing < 10/100 ml. The pres-ence of waterfowl and fecal contamination from a poultry farm resulted in higher Campylobacter levels About 50% of the isolates typed as C. Cellipoultry farm resulted in higher Campylobacter levels. About 50% of the isolates typed as C. oli were confirmed as C. jejuni by electrophoretic pattern (whole cell protein profiles). Campylobacter test strains survived only a few hours at 37 C and up to a few days at 20 C. Survival was up to several weeks in some cases at low temperatures. Survival in sewage sludge ranged from hours to 10 days. These results must be viewed in the light of the occurrence in Campylobacter of a viable nonculturable stage. The fractions of dead cells and of viable nonculturable cells is unknown under environmental conditions. The health risk posed by ronmental conditions. The health risk posed by viable nonculturable Campylobacter is also un-known. (See also W91-10612) (Doria-PTT) 91-10634

DISINFECTION OF SECONDARY EF-JENTS FROM SEWAGE TREATMENT PLANTS.

Bayerische Landesanstalt fuer Wasserforschung, Munich (Germany, F.R.)

Water Science and Technology WSTED4, Vol. 24, No. 2, p 343-346, 1991. 4 fig, 3 ref.

Descriptors: \*Bacteria, \*Disinfection, \*Secondary wastewater, \*Ultraviolet radiation, \*Wastewater treatment, Acinetobacter, Aerobic bacteria, Coliforms, Culturing techniques, Effluents, Fecal coliforms, Fecal streptococci, Germany, Munich, Pilot plants, Sewage bacteria.

Pilot plant experiments were conducted on the effect of ultraviolet (UV) irradiation on secondary effluent from a wastewater treatment plant near Munich (Germany). UV disinfection led to a good reduction of bacterial concentration. At a flow rate reduction of bacterial concentration. At a flow rate of 50 cu m/h, the logarithms of mean reduction rates were 4.2 for total coliforms, 4.3 for fecal coliforms, 3.8 for fecal streptococci, and 3.4 for standard plate count. At a flow rate of 150 cu m/h, the logarithms of mean reduction rates were 3.0 for total coliforms, 3.3 for fecal coliforms, 2.5 for fecal streptococci, and 2.4 for standard plate count. The reduction rates of total and fecal coliforms were similar. Fecal streptococci and plate count bacteria were less sensitive to UV irradiation than coliforms. The log reduction rate of fecal streptococci was about 0.5 lower and that of plate count bacteria about 0.8 lower than that of coliforms. Within the group of dominant aerobic wastewater bactethe group of dominant aerobic wastewater bacteria, the reduction rates differ more from one another than within the group of fecal indicator bacteria. Enterobacters ( $(g\ r)=3.5$ ) and strains of Acinetobacter ( $(g\ r)=3.3$ ) were most sensitive to UV irradiation. Coryneform bacteria showed the lowest reduction rate ( $(g\ r)=0.8$ ). Differing UV sensitivities of these bacteria led to a population shift under UV treatment. The results indicate that the application of UV disinfection in full-scale wastewater treatment plants is promising. Designing ultraviolet (UV) reactors for inactivation of viruses in treated wastewater requires field data on UV resistance of these organisms. It would therefore be desirable to have a simple model organism that can be assayed frequently, at low cost, and with rapid results. The F-specific RNA (FRNA) bacteriophages were investigated as potential process indicators for the design and monitoring of UV reactors. FRNA bacteriophages can be assayed in wastewater by simple and rapid methods. Their inactivation by UV radiation follows first-order kinetics and relatively simple formulas can describe the effect of UV absorbance by wastewater and the wavelength-dependent killing mulas can describe the effect of UV absorbance by wastewater and the wavelength-dependent killing efficiency of polychromatic lamps. Because the organisms can be grown in high concentrations, biological calibration of full-scale reactors requires only relatively small volumes of phage culture. Naturally occurring FRNA phages were more re-

### Waste Treatment Processes—Group 5D

sistant to UV than somatic coliphages, Escherichia coli, and fecal streptococci. The inactivation rate constant was almost equal to that of reoviruses, which underlines the suitability of FRNA phages as a process indicator for UV inactivation of viruses. A pure culture of MS2 was inactivated at a rate almost twice that of naturally occurring FRNA phages, indicating the necessity of designing reactors for practical applications on field data rather than laboratory experiments. ACTIVITY OF PERACETIC ACID ON SEWAGE INDICATOR BACTERIA AND VIRUSES, Interox S.A., Widnes (England). Research and De-

velopment.
M. G. C. Baldry, M. S. French, and D. Slater.
Water Science and Technology WSTED4, Vol.
24, No. 2, p 353-357, 1991. 3 tab, 11 ref.

Descriptors: \*Bacteria, \*Chlorine, \*Disinfection, \*Peracetic acid, \*Viruses, \*Wastewater treatment, Acidity, Bacteriophage, Bioindicators, Comparison studies, Organic matter, Oxygen, Performance evaluation, Yeasts.

Studies were undertaken to establish the comparative effects of peracetic acid (PAA) and chlorine on bacteria and viruses. Results show that, against both bacteria and phage, PAA is very effective in clean systems, and retains some activity in the presence of organic soiling. Although the activity of PAA was best under mildly acidic conditions, of PAA was best under mildly acidic conditions, good antimicrobial action was also seen at neutral pH. The poliovirus used was much more resistant to PAA than were the phages and the bacteria. However, the concentration of PAA required for a given reduction in viral numbers is little changed in the presence of organic matter. For example, the concentration of PAA required to bring about a 99.99% reduction in the concentration of poliovirus in the presence of yeast extract was typically 1.5 to 2 times the concentration necessary in a rus in the presence of yeast extract was typically 1.5 to 2 times the concentration necessary in a clean system. In the presence of yeast extract, identical performances against poliovirus were obtained using 2,000 mg/L available chlorine or 2,250 mg/L PAA (470 mg/L available chlorine or 2,250 mg/L PAA (470 mg/L available chlorine or 10 minutes, or 750 mg/L PAA (160 mg/L available oxygen) with a contact time of 10 minutes, or 750 mg/L available over a five minute contact time were 2,000 mg/L available chlorine compared to 94-113 mg/L PAA (20-24 mg/L) available oxygen). These results indicate that PAA is effective against bacteria, phage, and viruses. In contrast to chlorine, PAA is little affected by organic matter, and viral inactivation continues up to one hour after PAA addition. (See also W91-10612) (Doria-PTT) W91-10682)

OCCURRENCE OF V. CHOLERAE 0:1 NON-TOXIGENIC IN WASTEWATERS FROM SAO PAULO, BRAZIL.

In the State of Sao Paulo, Brazil, a program of cholera surveillance was undertaken between September 1974 and December 1983, analyzing sewage samples for the presence of Vibrio cholerae 0:1 to evaluate the possible circulation of this agent in the community. Of 12,867 samples analyzed, four were positive for V. cholerae. Five strains were identified, all of which were negative for cholera enterotoxin (CT) when assayed in Y-1 categorical lines. No cholera cases were reported. tor cholera enterotoxin (C1) when assayed in Y-1 adrenal cell lines. No cholera cases were reported in the country. Two of the strains isolated were studied and determined to be hemolytic and resistant both to phage IV (specific for classical strain) and to phage specific for the eltor strain. They

were sensitive to polymixin B and negative by the Voges-Proskauer test, and presented a strong reaction with antiseral 0:1. However, they also reacted tion with antiseral 0:1. However, they also reacted with antiserum Inaba, so were not a typical eltor biovar. Pathogenicity was evaluated for CT in rabbit ileal loop, rabbits, and suckling mice, and by enzyme-linked immunoassay (ELISA) and radioimmunoassay. Results were, in general, negative. The isolation of nontoxigenic V. cholerae Olf from environmental samples is not rare. Many exfrom environmental samples is not rare. Many explanations have been proposed to explain this phenomenon, including mutations. The potential hazard of public health due to V. cholerae 0:1 may be contact occurs through use of sewage-contaminated water for crop irrigation or by other means. (See also W91-10612) (Doria-PTT) W91-10685

CLOSTRIDIUM PERFRINGENS, AS AN INDI-CATOR MICROORGANISM FOR THE EVAL-UATION OF THE EFFECT OF WASTEWATER AND SLUDGE TREATMENT SYSTEMS.

Azabu Univ., Sagamihara (Japan). Dept. of Environmental Technology. T. Hirata, K. Kawamura, S. Sonoki, K. Hirata. and

Water Science and Technology WSTED4, Vol. 24, No. 2, p 367-372, 1991. 3 fig, 2 tab, 23 ref. Ministry of Education, Science and Culture (Japan) Grant 62550402.

Descriptors: \*Bacterial analysis, \*Bioindicators, \*Clostridium, \*Disinfection, \*Monitoring, \*Path of pollutants, \*Sludge treatment, \*Wastewater treatment, \*Water quality, Bacteria, Chlorine, Feces, Heterotrophic bacteria, Hydrogen ion concentration, Lakes, Rivers.

A series of field investigations were performed to determine the incidence of several indicator microorganisms and Clostridium perfringens in order to evaluate the effectiveness and significance of C. perfringens as an indicator microorganism for fecal pollution. Water samples were collected from several stages of wastewater and sludge treatment eral stages of wastewater and sludge treatment processes and natural water bodies such as rivers and lakes. In addition, laboratory studies were performed to assess the chlorine resistance of these microorganisms. The contact time required for 99% inactivation of C. perfringens with 0.1 mg/L free chlorine at pH 7 was found to be 5 minutes for pure cultured cells; chlorine resistance of C. perfringens indigenous to sewage was 3 to 5 times higher. A proportional relationship was found behigher. A proportional relationship was found be-tween the density of C. perfringens and that of tween the density of C. perfringens and that of heterotrophic bacteria in environmental waters. Clostridium perfringens was least reduced in almost all unit processes, compared with the other indicator microorganisms studied. Results suggest that C. perfringens is an attractive indicator microganism for the assessment of microbial removal in wastewater and sludge treatment and for the evaluation of the quality of treated wastewater discharged to rivers or reused. As the quantity of this microorganism in human and animal feces is this microorganism in human and animal feces is relatively small, a concentration method must be developed to permit its use for the quantitative evaluation of microbial pollution. SALMONELLA DETECTION IN SEWAGE WATERS USING FLUORESCENT ANTI-WATERS BODIES.

Rennes-1 Univ. (France). Lab. de Microbiologie Pharmaceutique.

J. Minet, C. Desmonts, M. Pommepuy, and M.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 373-376, 1991. 4 fig. 5 ref.

Descriptors: \*Bacterial analysis, \*Chlorination, \*Disinfection, \*Fluorescence, identification, \*Salmonella, \*Wastewater analysis, Bacteria, Chlorine, Filtra-tion, Particulate matter, Wastewater, Water quality

Human pathogens persist in the aquatic environ-ment through a viable but nonculturable stage.

Chlorine injury might be lethal for only a small fraction of exposed cells, especially when bacteria are attached to suspended particulate matter. A direct detection procedure was therefore designed for Salmonella followup after chlorination of raw of the control of the contr effluent in an experimental sewage plant. Fluores cein isothiocyanate conjugated antirabbit immuncein isothiocyanate conjugated antirabbit immun-oglobulin was used for indirect fluorescent anti-body staining. Direct viable count (DVC) was modified as follows. Wastewater samples were fli-tered directly through black Nucleopore filters of pore size 3 microns for enumeration of Salmonella pore size 3 microns for enumeration of Salmonella attached to particulate matter; 0.2 microns for total Salmonella on whole sample and free Salmonella previously passed through 3 micron filters. In chlorinated wastewater, 5% to 31.5% of Salmonella were found to be substrate responsive in whole samples. The percentage of substrate responsive cells is <4% among free Salmonella. Six to 30 percent of Salmonella attached to particulate mater (retained on 3 micron filters) are substrate responsive. Direct detection of nathogens, rather, than (retained on 3 micron inters) are substrate responsive. Direct detection of pathogens, rather than reliance on culture methods, may more accurately assess water quality. Chlorination is inefficient for suppressing viability of Salmonella attached to particulate matter in wastewater. (See also W91-10612) (Doria-PTT) W91-10687

DESTRUCTION OF FAECAL BACTERIA, ENTEROVIRUSES AND OVA OF PARASITES IN WASTEWATER SLUDGE BY AEROBIC THERMOPHILIC AND ANAEROBIC MESOPHILIC DIGESTION,

Water Research Centre, Medmenham (England). E. G. Carrington, E. B. Pike, D. Auty, and R Morris.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 377-380, 1991. 2 tab, 16 ref. UK Dept of the Environment Contract PECD 7/7/261.

A new sludge treatment plant at Harrogate South Sewage Treatment Works (England) is designed to handle up to 4 tons dry solids (ds) daily. Sludge is thickened continuously up to 8% (ds) and is then treated in parallel anaerobic mesophilic (AD) and thermophilic aerobic digestion (TAD) plants, each with a maximum working volume of 530 cu m. Microbiological studies were carried out to compare the destruction of pathogase and facel indicated. Microbiological studies were carried out to com-pare the destruction of pathogens and fecal indica-tor bacteria. The AD plant operated with a mean retention of 26 days at 34 C and achieved 49% reduction of volatile solids. The TAD plant oper-ated with a mean retention of 28 days at 35 C and reduced volatile solids by 35%. Operation was on a pump in-pump out cycle, guaranteeing 4 h reten-tion time for all sludge. The disinfecting ability of TAD exceeded that of AD, since it reduced counts of Enterobacteriaceae, thermotolerant coliforms, and fecal streptococci to below 103/100 ml, rendered cytopathic enteroviruses undetectable, and destroyed viability of Ascaris suum ova within 4 h. The AD process reduced bacterial counts by 90% and enteroviruses by 99%, but had no effect upon viability of Ascaris ova. (See also W91-10612) (Author's abstract) W91-10688

CONTRIBUTION FOR THE STUDY OF NEW PATHOGENIC INDICATORS REMOVAL PATHOGENIC INDICATORS FROM W. S. P. IN PORTUGAL.

um, Fecal coliforms, Fecal streptococci, Heterotrophic bacteria, Lagoons, Precipitation, Pseudomonas, Solar radiation, Temperature.

The use of waste stabilization ponds (WSP) is increasing in Portugal. The kinetics of pathogen removal by this nonchemical system differs according to the conditions of treatment and climatic cording to the conditions of treatment and climatic and ecological conditions. Die-off kinetics were studied in WSPs in Portugal using indicators other than the classic ones (fecal coliforms, fecal strepto-cocci, Clostridium perfringens, Pseudomonas aeruginosa, and heterotrophic bacteria). Removal kinetics were found to be different for each organism and in each type of pond. Multiple indicators should be used, as none of the indicators can be considered ideal. Specific climatic conditions are important for each organism and each type of reactor. The most important climatic influence on microbial die-off is precipitation; temperature, and solar radiation are also important. The influence of solar radiation are also important. The influence of climatic factors is stronger in anaerobic ponds than in facultative ponds, and least evident in maturation lagoons. A cumulative effect is very clear for the whole system. The dominant pattern for each climatic factor is different, being hyperbolic for daily precipitation influence and dominantly exponential for temperature and solar radiation (daily averages). These climatic influences, added to those from ecological sources, may help explain interannual and interregional differences observed among actual ponds. (See also W91-10612) (Doria-PTT)

DYNAMICS OF NON-01 VIBRIO CHOLERAE IN EXPERIMENTAL SEWAGE STABILIZATION PONDS UNDER ARID MEDITERRANE-AN CLIMATE.

AN CLIMATE.
Cadi Ayyad Univ., Marrakech (Morocco). Lab. de
Microbiologie.
J. Lesne, B. Baleux, A. Boussaid, and L. Hassani.
Water Science and Technology WSTED4, Vol.
24, No. 2, p 387-390, 1991. 3 fig, 1 tab, 14 ref.

Descriptors: \*Arid lands, \*Bacteria, \*Morocco, \*Stabilization ponds, \*Vibrio, \*Wastewater treat-ment, Bioindicators, Fecal coliforms, Fecal streptococci, Populations, Pseudomonas, Seasonal variation, Temperature. Radiation

The temporal dynamics of non-01 Vibrio cholerae and pollution indicator bacteria were studied in an experimental stabilization pond system consisting of two successive basins in an arid Mediterranean of two successive basins in an and Mediterranean climate (Marrakech, Morocco). The same seasonal cycle was found in the inflow, in the first pond, and in the outflow: low levels of V. cholerae during the cold season (December to March) and high level during the warm season (April to Nober). Temporal evolutions of non-01 V. cholerae are positively correlated with temperature throughout the treatment plant. This could indi-cate control of this bacterial population by climatic factors acting through physical, chemical, and bio-logical variables. However, temporal evolutions of non-01 V. cholerae are highly correlated with sev-eral environmental factors in the first basin only, and the relations are lost in the second basin. There and the relations are lost in the second usain. Their is no correlation with transmitted radiant energy throughout the treatment plant. In the ponds, temporal evolutions of non-01 V. cholerae are negatively correlated with fecal contamination indicatively correlated with fecal contamination indicators (fecal coliforms and fecal streptococi) and are not correlated with Pseudomonas aeruginosa. In the inflow, non-01 V. cholerae counts are correlated with P. aeruginosa and not with fecal contamination indicators. The treatment process is ineffective on the non-01 population: there is no bacterial reduction during the hot season, when other pollution indicators are well reduced, and there is no significant decrease during the cold season. WASTE STABILIZATION PONDS IN GRAND CAYMAN, CAYMAN ISLANDS.
Water Authority, George Town (Cayman Islands).

G. L. Frederick.
Water Science and Technology WSTED4, Vol. 24, No. 2, p 391-394, 1991. 7 fig, 2 tab, 3 ref.

Descriptors: \*Cayman Islands, \*Odor control, \*Stabilization ponds, \*Wastewater treatment, Aerators, Anaerobic conditions, Biological oxygen demand, Color, Conductivity, Costs, Economic aspects, Fecal coliforms, Hydrogen sulfide, Salinity, Sulfates, Sulfides, Water table.

The Cayman Islands Water Authority selected waste stabilization ponds to treat the sewage from the West Bay Beach sewerage project because of the anticipated low operational and maintenance the anticipated low operational and maintenance cost. The two facultative ponds are operated in parallel, with the effluent of both going to the first maturation pond, and from there to a final maturation/polishing pond. High salinity in the incoming sewage poses a financial problem, since the final effluent cannot be sold for irrigation. Rising electrical conductivity was identified in the effluent since June 1988. Contributing factors include the flooding of sewers with seawater during Hurrigane. since June 1988. Contributing factors include the flooding of sewers with seawater during Hurricane Gilbert in September 1988; minor saline intrusion in sewers laid below the groundwater table; the use of seawater for toilet flushing; and septage disposal. Odor became a problem in October 1988. Sulfate levels have varied between 50 and 360 mg/L, and hydrogen sulfide has been detected in the final pond. However, performance measured by biologi-cal oxygen demand and fecal coliform removal do cal oxygen demand and react conform removal do not always coincide with high levels of sulfates and sulfides. Odor and color problems improved following the installation of 8 diffuse aerators in each of the two facultative ponds in October 1989. However, overall pond performance has not improved. Low levels of hydrogen sulfide are frequently found in the facultative pond, indicating that they are operating anaerobically from time to time. (See also W91-10612) (Doria-PTT) W91-10691

SURVIVAL OF PATHOGENIC BACTERIA IN AN ADVERSE ENVIRONMENT.

Technion - Israel Inst. of Tech., Haifa. Sherman Center for Research in Environmental and Water Resources Engineering. A. Barzily, and Y. Kott.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 395-400, 1991. 1 fig, 5 tab, 13 ref.

Descriptors: \*Enteric bacteria, \*Pathogenic bacteria, \*Stabilization ponds, \*Wastewater treatment, Bacteria, Effluents, Immunoassay, Salmonella, Shigella, Survival, Temperature, Temperature effects.

Pathogenic bacteria are known to be sensitive to changes in environmental conditions. This applies to Enterobacteriaceae as well, where optimum temperatures are 37 C. Wastewaters of various qualities are hostile environments to these bacteria. quanties are nostite environments to these bacteria. The influence of temperature was investigated on die-off of enteric bacteria in waste stabilization ponds within the temperature range of 40-60 C. Survival of indicator microorganisms at the control pond effluent was higher than at increased temperature pond effluent (40, 50, 60 C). Survival percentages of the indicators at the elevated temperature and compared to the option leaves percentages of the inducators at the elevated temperature pond compared to the control pond were 0.12% to 73.33%. Dialysis bags containing the pathogenic bacteria Salmonella typhimurium and Shigella sonnei were placed in the ponds. The numbers of the pathogenic bacteria decreased by a few orders of magnitude within days, depending on the temperature and on the strain. After certain periods of time, the bacteria held in the heated pond, and in some instances in the control pond, lost their ability to agglutinate with specific anti-bodies. This phenomenon requires further rebodies. This phenomenon requires further re-search; it might indicate an unknown heat survival mechanism of the pathogenic bacteria in adverse environments. COMPARATIVE STUDY ON ADSORPTION MECHANISMS OF RNA-F-SPECIFIC COLI-PHAGES AND POLIOVIRUS IN ACTIVATED SLUDGE PROCESS.

Tokyo Univ. (Japan). Dept. of Urban Engineering. A. Ketratanakul, S. Ohgaki, and K. Yano. Water Science and Technology WSTED4, Vol. 24, No. 2, p 407-412, 1991. 7 fig, 10 ref.

Descriptors: \*Activated sludge process, \*Bacterio-phage, \*Indicators, \*Nucleic acids, \*Poliovirus, \*Viruses, \*Wastewater treatment, Acids, Adsorp-tion, Bases, Coliphages, Fate of pollutants, Glucose, Hydrogen ion concentration, Pathogens,

The adsorption mechanisms of RNA-F-specific coliphages, Q-beta, and poliovirus 1 in the activated sludge process was studied experimentally. The mechanisms of Q-beta and poliovirus associated with microbial flocs were attributable to the pH change in the system which was caused by either microbial activity during glucose uptake or the added acids and alkalis. When the pH of the activated sludge system was controlled by acids and alkalis rather than by microbial activity, the adauxains rather than by microma activity, the as-sorption of Q-beta or poliovirus was not observed unless the hydrogen ions went closely to Q-beta and poliovirus surfaces, resulting in a change in the pH or potential of the surface. If the pH was controlled closely to the isoelectric point (pls) of either Q-beta or poliovirus, the adsorbed numbers increased. The mechanisms of O-beta and poliovirus associated with microbial flocs were likely to rus associated with microbial nocs were likely to be similar, the only difference being the pI level of each. Therefore, given information on the pI value of a pathogenic virus, one could, in general, predict the fate of the particular virus in activated sludge based on coliphage Q-beta. Q-beta was found to be more tolerant to stress than poliovirus, since Q-beta remained stable for a week in a batch since Q-beta remained stable for a week in a batch reactor (activated sludge process). By contrast, poliovirus was reduced by about 0.8 log in three days in the same reactor. RNA-F-specific phage Q-beta proved to be a suitable model virus in wastewater, due to the similarity of association mechanisms with solids as well as high relative resistance to environmental conditions in the waste treatment process. NEW DEVELOPMENTS IN PROCESSING OF SLUDGES AND SLURRIES.

Proceedings of a Round Table Seminar held April 22, 1985 in Bithoven, The Netherlands. Elsevier Science Publishing Co., New York. 1986. 89p. Edited by A.M. Bruce, P. L'Hermite, and P.J.

Descriptors: \*Farm wastes, \*Manure, \*Sludge di-gestion, \*Sludge disposal, \*Sludge treatment, \*Slurries, \*Wastewater treatment, Animal wastes, Conferences, Dewatering, Fuel, Reviews, Sludge, Sludge drying, Sludge stabilization, Sludge utilization, Solid waste disposal, The Netherlands.

This book contains the proceedings of a round-table meeting held at Bithoven, The Netherlands, in April 1985 under the auspices of the Commis-sion of the European Communities' Concerted Action on the treatment and use of organic sludges and liquid agricultural wastes. Working Party No. 1 of the Concerted Action has the task Party No. 1 of the Concerted Action has the task of coordinating nationally funded research on the processing of sewage sludges and animal slurries. New research developments in the field of sludge and slurry processing were reviewed and discussed. Three of the papers presented relate to sludge dewatering methods, two relate to methods of perchic stabilization of sludge and another paper. of aerobic stabilization of sludge and another paper describes a novel development in the conversion of sewage sludge to a usable fuel. The results of examining the influence of sludge processing tech-niques on some of the important organic micropol-lutants in sewage sludges are described in other contributions. The remaining paper deals with research on new ways of processing animal manures. (See W91-10700 thru W91-10707) (VerNooy-PTT) W91-10699

APPLICATION OF ELECTRICAL FIELDS TO THICKEN AND DEWATER SEWAGE SLUDGES.

Institut de Recherches Hydrologiques, Nancy (France).

IN: New Developments in Processing of Sludges and Slurries. Elsevier Science Publishing Co., New York. 1986. p 3-13. 24 ref.

Descriptors: \*Dewatering, \*Electric currents, \*Electrochemistry, \*Sludge drying, \*Sludge thickening, Consolidation sedimentation, Electrophoresis, Incineration, Particulate matter, Sludge, Sludge filters, Sludge treatment, Suspended solids.

Sewage sludges are made up of small solid parti-cles suspended in an aqueous solution. Application of an electric field can induce solid and liquid or an electric field can induce soind and inquid phases to move relative to each other. The pros-pects for applying electric fields for solid/liquid separation in urban sewage sludges are discussed. The electrochemistry of the interfaces and electro-kinetic effects are detailed, and basic laws of electrophoresis and of electro-osmosis are summarized. Applications of electric fields include: to speed up Applications of electric fields include: to speed up-sedimentation and gravity thickening of sludges; to concentrate sludges by filtering without any cake production; and to dewater liquid sludges until a solid residue is produced. Performance data and power consumption is listed for each of the experi-mental devices designed and tested. (See also W91-10699) (Author's abstract) W91-10700

INFLUENCE OF POLYELECTROLYTE CHARACTERISTICS ON SLUDGE CONDITIONING (LAB EVALUATIONS).

(LAB EVALUATIONS).
Istitute of Ricerca sulle Acque, Bari (Italy).
L. Spinosa, V. Lotito, F. Lore, and G. Barile.
IN: New Developments in Processing of Sludges and Slurries. Elsevier Science Publishing Co., New York. 1986. p 14-26. 4 fig, 4 tab, 13 ref.

Descriptors: \*Dewatering, \*Polyelectrolytes, \*Sludge conditioning, \*Sludge drying, \*Sludge treatment, Centrifugation, Chemical properties, Molecular structure, Sludge, Sludge filters, Sludge thickening, Weight.

In recent years polyelectrolytes have found in-creased utilization for sewage sludge conditioning before mechanical dewatering. Molecular weight and charge density are the most important polye-lectrolyte characteristics which affect their effec-tiveness. However, little information is found in the literature on which characteristics polyelectrolytes should have to obtain the most effective sludge conditioning for each dewatering technique studge conditioning for each dewatering technique adopted. Laboratory tests were carried out to study the influence of the above characteristics on sludge conditioning as a function of the type of dewatering machine. The filter press, belt press and centrifuge are the most utilized machines for and centringe are the most utilized macinnes for sewage sludge dewatering. Results showed that polyelectrolytes with low molecular weight and high charge density are preferable for conditioning sludge to be filter-pressed, with medium molecular weight and high charge density for sludge to be dewatered by belt press, and with medium molecular weight and medium charge density for sludge. dewatered by beit press, and with medium molecular weight and medium charge density for sludge to be centrifuged. These results allow a first rough selection among the different polyelectrolyte types available on the market to be done, thus limiting the number of tests for selecting the best type for a certain application. CHP-FILTER PRESS-THE FIRST CONTINU-OUS HIGH-PRESSURE FILTER PRESS.

Abwasser-Abfall-Aquatechnik, Darmstadt (Germany, F.R.).

In: New Developments in Processing of Sludges and Slurries. Elsevier Science Publishing Co., New York. 1986. p 27-35. 5 fig, 3 tab, 1 ref.

Descriptors: \*Dewatering, \*Sludge drying, \*Sludge filters, \*Sludge treatment, Dry matter, Mechanical equipment, Sludge, Sludge cake, Sludge solids, Sludge thickening.

In order to obtain satisfactory dewatering results in many cases of application, a considerable amount of equipment, and therefore high investment costs, of equipment, and therefore high investment costs, as well as a non-continuously working procedure, had to be accepted. To overcome these problems, the CHP-filter press, or continuous working high pressure filter press, was developed. Using this press, the pressure on a suspension to be dewatered can be continuously increased and therefore dewatering results which were only previously attainable using chamber, plate or membrane filter press can be obtained. The new continuous working high pressure filter press is built in six different types according to various applications. Based on the high and long lasting active pressures, the new press achieved final solid matter qualities in the filter cake under all applications tested so far. Since sewage sludge solid matter results ranged between 35 to 55% dry matter, the content of industrial suspensions were partly dewatered up to more suspensions were partly dewatered up to more than 75% dry matter continuously. ### DUTCH APPROACH TO MANURE PROCESS-

Government Agricultural Waste Water Service, Arnhem (Netherlands). P. J. W. ten Have.

In: New Developments in Processing of Sludges and Slurries. Elsevier Science Publishing Co., New York. 1986. p 36-46. 5 fig, 4 tab, 5 ref.

Descriptors: \*Animal wastes, \*Farm wastes, \*Fer-tilizers, \*Manure, \*Sludge disposal, \*Sludge treat-ment, \*Slurries, \*The Netherlands, \*Waste treat-ment, Aeration, Consolidation sedimentation, Dewatering, Pigs, Poultry, Sludge, Sludge condi-tioning, Sludge digestion, Sludge drying, Sludge

The last twenty years has shown a tremendous growth in the Dutch production of pig and poultry meat. This has been accompanied by an equivalent amount of animal excrements, which, until now, has been spread on agricultural land. Within a short time laws will be introduced which will allow maxima to be set on the amount of fertilizer applied to agricultural land. This will result in a sharp increase in the transport of animal slurries to farms with a shortage of minerals. Since there is only a small demand for veal calf manure most of it will have to be purified. Plans to do this have been developed at a central plant at Elspeet. After coarse screening the manure is transferred into a ocarse screening the manure is transferred into a balancing basin, and the daily volume of manure to be treated is pumped into the aeration basin. About 20 hours later aeration is stopped, and after 1 hour sedimentation the effluent is discharged to the sedimentation the effluent is discharged to the sewer system. Sludge is periodically used as fertilizer. For the longer term, it is expected that surpluses in pig manure will have to be treated as well. In the Sterksel experimental pig station process, undigested manure is conditioned with iron chloride and polyelectrolyte, and then separated and dewatered. The filtrate is purified in an activated sludge process and then the effluent is treated by reverse osmosis. For the Agricultural University of Wageningen process, the first step is anaerobic digestion of the complete flow. Next, is addition of lime, iron chloride and polyelectrolyte. After this, separation and dewatering is carried After this, separation and dewatering is carried out, with subsequent ammonia stripping and reout, with subsequent ammonia stripping and re-verse osmosis treatment. Large-scale processing of pig manure will really be possible only when there is no doubt about the disposal of the residual products, which means where, in what form, and for what price. AEROBIC THERMOPHILIC DIGESTION OF PRE-THICKENED SLUDGE USING AIR. B. Paulsrud, and G. Langeland. IN: New Developments in Processing of Sludges and Slurries. Elsevier Science Publishing Co., New York, 1986, Pd.93.8 4 66, At ab. 9 ref. York. 1986. p 49-58. 4 fig, 4 tab, 9 ref.

Descriptors: \*Aerobic digestion, \*Sludge digestion, \*Sludge thickening, \*Sludge treatment, \*Thermophilic bacteria, Aeration, Norway, Odors,

Operating costs, Pilot plants, Sieves, Sludge, Sludge conditioning, Sludge stabilization.

In 1983 the Danish company JANCA introduced In 1983 the Danish company JANCA introduced on the Norwegian market a new version of the aerobic, thermophilic digestion process using a special device (vibrating sieve) for thickening the raw sludge up to 8 to 10% before digestion. Pilot scale studies of (The JANCA-process) aerobic, thermophilic digestion of pre-thickened sludge using air were performed for seven weeks at the HIAS sewage treatment plant in Norway. By batch operation of the process with sludge draw and fill every second day, temperatures above 60 C could be maintained in the single stage reactor for approximately 30 hours. The treated sludge was satisfactorily santitized, but detention time was too short for rendering the sludge stable and odor free. The vibrating sieve did not function properly with the mixed primary-activated-chemical (A1) sludge and should therefore be replaced by another type of simple equipment that can produce a sludge of 8 to 10% dry solids (DS) (e.g., dewatering contain-e). The operating cost of the process (energy and polymer) is estimated to be about 150 NOK/ton DS, and the capital cost for a plant of 2,100 tons DS/year is about 2 million NOK (1984). (See also W91-10699) (Author's abstract) on the Norwegian market a new version of the W91-10704

### SLUDGE MANAGEMENT BY THERMAL CONVERSION TO FUELS.

H. W. Campbell, and T. R. Bridle. IN: New Developments in Processing of Sludges and Slurries: Elsevier Science Publishing Co., New York. 1986. p 67-78. 3 fig. 2 tab, 9 ref.

Descriptors: \*Fuel, \*Heat treatment, \*Sludge treatment, \*Sludge utilization, \*Waste management, Canada, Dewatering, Fertilizers, Land application, Oil, Sludge, Sludge digestion, Sludge disposal, Sludge drying, Waste treatment, Wastewater

The philosophy of sludge management in the sewage treatment industry must respond to changes in processing costs and environmental requirements. As overall costs increase, the efficiency of sludge management must be increased by either upgrading the existing scheme or introducing new technology. Low temperature conversion of sludge to fuel appears to have considerable potential as a viable new technology. Experimental work carried out at Environment Canada's Wastewater Technology Centre used batch and continuous reactors to evaluate this technology at continuous reactors to evaluate this technology at bench-scale. Tests on a number of mixed raw sludges (primary plus waste activated) resulted in the following yield: oil, 22 to 25%; char, 50 to 60%; non-condensible gas, 10 to 12%; and reaction water 5 to 12%. The impact of a number of sludge treatment alternatives that are of concern include: application of digested sludge on agricultural land; digestion, dewatering and incineration of sludge; upgrading of sludge dewatering equipment to create an energy surplus upon sludge incineration; and conversion of sludge to oil. Factors such as energy efficiency, flexibility, and public acceptance of the method must also be considered. Environment Canada's long term plans are to demonstrate of the method must also be considered. Environ-ment Canada's long term plans are to demonstrate the technology for conversion of sludge to oil by construction of a 25 ton facility. The first phase of this demonstration study is currently underway with the development of the pre-engineering data, identification of suitable sites and a thorough as-sessment of the process economics. ACCUMULATION OF REFRACTORY 4-NON-YLPHENOL DURING MESOPHILIC ANAER-OBIC SLUDGE STABILIZATION,

### **Group 5D—Waste Treatment Processes**

Eidgenoessische Anstalt fuer Wasserversorgung, Abwasserreinigung und Gewaesserschultz, Due-bendorf (Switzerland).

M. Tschui, P. H. Brunner, and W. Giger. IN: New Developments in Processing of Sludges and Slurries. Elsevier Science Publishing Co., New York. 1986. p 79-83. 4 fig, 6 ref.

Descriptors: \*Anaerobic digestion, \*Nonionic surfactants, \*Phenols, \*Sludge stabilization, \*Wastewater treatment, Biodegradation, Sludge, Sludge digestion, Sludge treatment.

4-Nonylphenol polyethoxylates are widely used nonionic surfactants which occur in municipal wastewaters. Anaerobically stabilized sewage sludges were found to contain high concentrations (0.45 to 2.5 g/kg dm) of toxic 4-nonylphenol. Two sets of experiments were performed: the anaerobic formation of 4-nonylphenol was examined in a continuous laboratory fermenter, and the anaerobic degradation of 4-nonylphenol was investigated by batch experiments. The experiments confirmed the formation of 4-nonylphenol by anaerobic mesophilic digestion of sewage sludge containing 4-nonyl-phenol monooxylates (NP1EO) and diethoxylates phenol monooxylates (NPIEO) and diethoxylates (NP2EO). When the fermenter was operated at a residence time of 20 days, approximately 60% of NPIEO and NP2EO were degraded and NP increased by a factor of 2. It was not possible to determine if nonylphenol was strictly refractory under anaerobic conditions by the batch experi-ments which were performed. Therefore, the models used assumed no further degradation of 4-nonlyphenol in the continuous fermenter. Preliminonyipation in the Collimanous Fernitude: Ferning arry results of a field investigation into the fate of 4-nonylphenol polyethoxylates during aerobic and anaerobic mesophilic and thermophilic stabilization indicate that the degradation products formed by the processes are significantly different. ### ENVIRONMENTAL FEASIBILITY OF USING WETLANDS TO TREAT RUNOFF POLLU-TION.

Naval Ocean Systems Center, San Diego, CA. L. E. Gadbois.

Available from the National Technical Information Available from the National Technical Information Service, Springfield, VA. 22161, as AD-A215 040. Price codes: A03 in paper copy, A01 in microfiche. Technical Report 1321, October 1989. 31p, 2 tab, 25 ref. 2 append.

Descriptors: \*Environmental impact, \*Wastewater treatment, \*Wetlands, \*Wetlands treatment, Biochemical oxygen demand, Ecological effects, Heavy metals, Military installations, Nonpoint pollution sources, Nutrients, Organic compounds, Runoff.

Chemical and ecological characteristics of wetland types commonly occurring in and around Navy bases are reviewed. The natural wetland processes oases are reviewd. The initial weunal processors are examined from the perspective of their capac-ity to remediate nonpoint source pollution (NPSP). The ecological habitat value of wetlands is iterat-ed, as are the habitat value changes resulting from ed, as are the manula value changes resulting from pollution loading. Wetlands can assimilate small loading rates of nutrients, biochemical oxygen demand (BOD), suspended solids, bacteria and degradable petroleum components, and provide valuable ecological habitat. Heavier loadings will damage the marsh, reduce its habitat value, and exceed the assimilative capacity. Nondegradable contaminants (heavy metals, some organics) may be contained in the marsh. Over the short-term, be contained in the marsh. Over the short-tern, this will ease the chronic exposure impact to adjacent recipient water, but over the long-term a toxic waste dump may develop. The morphology of the marsh has a major impact on the remediation effectiveness. Flushing, which sustains the marsh, also removes some pollutants before ample time for degradation has occurred. There is a large knowledge gan to bridge before the exological impact of edge gap to bridge before the ecological edge gap to bridge before the ecological impact of a chemically characterized effluent added to a marsh can be confidently predicted. Wetlands may be the best available technique for some runoff situations and be disastrous for others. Careful research will clarify those cases for which this technique is and is not appropriate. Wetlands will not be a universally applicable method for runoff

remediation, but they should be the technique of choice for some situations. (Lantz-PTT) W91-10737

#### ROLE OF BIOTECHNOLOGY IN THE TREAT-MENT OF SLUDGES. GEOTHERMAL RESIDUAL

Brookhaven National Lab., Upton, NY. Dept. of Applied Science.
E. T. Premuzic, and M. S. Lin.

E. 1. Premuzic, and M. S. Lin. Available from the National Technical Information Service, Springfield, VA. 22161, as DE89-017609. Price codes: A02 in paper copy, A01 in microfiche. Report No. BNL-42361, May 1988. 4p. 5 fig, 8 ref. DOE Contract No. DE-AC02-76CH00016.

Descriptors: \*Biotechnology, \*Geothermal wastes, \*Sludge treatment, \*Waste disposal, \*Waste treatment, \*Wastewater treatment, Biofilm reactors, Brines, Chemical precipitation, Chromium, Electric powerplants, Geothermal water, Metals, Toxic

Powerplants which use geothermal heat to generate electric power produce a residual sludge in large quantities. This material precipitates from supersaturated brines and contains toxic metals, some of which are present in concentrations exsome of which are present in concentrations ex-ceeding the non-hazardous waste disposal regula-tions. Disposal of this waste as hazardous waste is costly. Work in this laboratory has shown that a biotreatment of the geothermal waste in which toxic metal resistant acidophilic organisms are used, can serve as a basis for a new biotechnology for the detayification of geothermal residual brine for the detoxification of geothermal residual brine sludges. Phase one studies have shown that an economically and technically feasible biotechnology can be developed. The efficiency of this technology depends on a number of parameters such as the bioreactor design residence the the bioreactor design, residence time, and the number and concentration of toxic metals to be removed. Further, the process, while rendering a detoxified material, produces a liquid phase which is enriched in toxic metals. This aqueous phase can be reinjected into the wells, or processed for the recovery of toxic metals, some of which are commercially valuable; for example, chromium. A par-allel study in this laboratory has shown that a combined chemical and biochemical process for the recovery of these metals may also be feasible. (Author's abstract) W91-10744

# AEROMONAS SPECIES STABILIZATION PONDS IN THE ARID REGION OF MARRA-KESH, MOROCCO, AND RELATION TO FECAL-POLLUTION AND CLIMATIC FAC-

Cadi Ayyad Univ., Marrakech (Morocco). Lab. de Microbiologie. A. Boussaid, B. Baleux, L. Hassani, and J. Lesne. Microbial Ecology MCBEBU, Vol. 21, No. 1, p 11-20, 1991. 5 fig, 2 tab, 30 ref.

Descriptors: \*Aeromonas, \*Bacterial analysis, \*Fecal coliforms, \*Morocco, \*Wastewater pollution, \*Wastewater treatment, Irrigation water, Pathogenic bacteria, Seasonal distribution, Species composition, Statistical analysis, Wastewater facilities, Water reuse, Water temperature.

Water samples were collected in two-week inter-Water samples were collected in two-week inter-vals from July 12, 1985 to December 23, 1987, for estimates of Aeromonas species in a waste treat-ment system located in the arid region of Marra-kesh. Fecal coliforms, temperature, and chemical oxygen demand were measured simultaneously with Aeromonas species densities. Statistical meth-ods were used to analyze the significance of aver-age differences and temporal patterns of Aero-monas species numbers. Removal of Aeromonas in the whole system did not exceed 1.14 log. Aero-monas densities showed significantly higher resismonas densities showed significantly higher resistance to the treatment process when compared with fecal coliforms; however, abundance of the two groups presented a similar seasonal change. The highest numbers occurred during the cold months, while the lowest appeared in the warm months. Statistical time-series analysis of the densities data showed the seasonal and cyclic distribution of Aeromonas in this treatment plant. These temporal

changes were simultaneously observed in all the changes were simulated by observed in all the stations investigated and were negatively correlated with temperature values. Aeromonas populations were dominated by A. caviae and A. hydrophila in the inlet samples. These two species were rapidly eliminated in the treatment plant. The temporal distribution of A. caviae was similar to the densities of Aeromanas and fecal coliforms. Seasonal fluctuations of abundance of Aeromonas were probably related to this species, which dominate the color of the nated in the winter samples but dropped during the summer. Meanwhile, A. sobria dominated all the final effluent samples. This greater survival of A. sobria and its known pathogenicity may limit the re-use of treated water for irrigation of fodder plants. ## COMPARISON OF PRESSURIZED AND GRAVITY DISTRIBUTION SYSTEMS FOR WASTEWATER TREATMENT.

Arkansas Univ., Little Rock, Dept. of Electronics and Instrumentatio

M. Gross, S. Neal, R. Muldoon, and B.

Proceedings of the Arkansas Academy of Science AKASAO, Vol. 44, p 53-55, 1990. 5 fig, 12 ref.

Descriptors: \*Biochemical oxygen demand, \*Filtration, \*Gravity filters, \*Pressure filtration, \*Wastewater facilities, \*Wastewater treatment, Ammonia removal, Nitrification, Nitrogen removal, Organic pollutants, Suspended solids.

Pressurized distribution of domestic wastewater over a sand filter surface achieves better treatment than gravity distribution. The pressurized distribu-tion system caused the filter to better remove organics and suspended solids. Pressurized distri-bution also caused the sand filter to achieve more complete nitrification than the filter having gravity complete intrincation that in the inter naving gravity distribution. Two slow sand filters 15.2 cm wide, 3.1 m long and 15.2 cm deep were built and loaded with domestic septic tank effluent for 250 days at a rate of 5.1 cm/day. Influent and effluent samples were collected and analyzed for five-day Bio-chemical Oxygen Demand (BOD-5), suspended chemical Oxygen Demand (BOD-5), suspended solids, ammonia-nitrogen, and nitrate-nitrogen. One filter received septic tank effluent through a 10 cm nominal diameter PVC perforated pipe via a distribution box dosed by a pump with gravity flow from the distribution box to the pipe. The other filter received water through a 2.5 cm nominal diameter PVC pipe having 0.4 cm diameter holes drilled 76.2 cm on center. The gravity distribution filter system achieved mean effluent values of 36.4 mg/l BOD-5, 19.8 mg/l suspended solids, 37.6 mg/l ammonia nitrogen, and 46.6 mg/l nitrate-nitrogen. The pressurized distribution system achieved 19.1 mg/l BOD-5, 12.2 mg/l suspended solids, 25.3 mg/l ammonia nitrogen, and 64.03 mg/l nitrate-nitrogen. Influent to the filters averaged 132.1 mg/l, 90.3 mg/l, 70.3 mg/l, and 3.6 mg/l BOD-5 suspended solids, ammonia nitrogen, and nitrate-nitrogen, respectively. (Author's abstract) W91-10845

### FATE AND EFFECTS OF SEMIVOLATILE OR-GANIC POLLUTANTS DURING ANAEROBIC DIGESTION OF SLUDGE.

Anaerobic digestion of primary and secondary sludge containing selected semivolatile organic pollutants was investigated. Typical digester operation was simulated with three, complete-mix, bench-scale digesters maintained at 35.5 C with a

### Waste Treatment Processes—Group 5D

30 day solids retention time. Two digesters were fed a primary and secondary sludge mixture pro-duced from wastewater spiked with 20 semivolatile organics from the CERCLA pollutant list. The remaining digester (the control) was fed a similar mixture of sludge, but with no added organics. mixture of sludge, but with no added organics. Operational parameters were monitored to compare the test and control units. All parameters were found to be within the limits of normal operation. Performance was near identical. An isotope dilution GC/MS method was employed for organics analysis of influent and effluent streams for all reactors. Steady-state fates of the organics were determined by mass balance. Twelve of the chemicals appear consistently and at steady state. Degradation was apparent for all components, with at least 10% of each parent compound partially or completely transformed. Sorption onto digester solids was an important removal mechanism. Results of organic analysis for the control digester highlight the effects of metabolic interferences. REMOVAL OF ACETATE FROM NSSC SUL-PHITE PULP MILL CONDENSATES USING THERMOPHILIC BACTERIA.

Valtion Teknillinen Tutkimuskeskus, Espoo (Fin-

land). Biotekniikan Lab. M. Perttula, M. Konradsdottir, J. Pere, J. K.

M. Feltuns, M. Kolliadsoutin, J. Fele, J. K. Kristjanson, and L. Viikari. Water Research WATRAG, Vol. 25, No. 5, p 599-604, May 1991. 4 fig. 4 tab, 19 ref. Nordisk Indus-trifond grant No. P 86013.

Descriptors: \*Acetates, \*Biological wastewater treatment, \*Pulp wastes, \*Sulfite liquors, \*Thermophilic bacteria, \*Wastewater treatment, Aerobic bacteria, Ammonia, Diatomaceous earth, Energy use efficiency, Industrial wastewater, Packed beds.

Treatment of sulfite mill condensates containing acetate and ammonia was studied using aerobic thermophilic bacteria at 65 C. A separate treatment at this relatively high temperature could save at this relatively high temperature of the renergy and decrease water consumption in the process. Experiments were carried out in packed bed bioreactors (vol. 0.1-0.3 cu dm) using media based either on condensate or on ammonium acebed intreactors (vol. 0.1-0.2 of um) using media based either on condensate or on ammonium ace-tate. Diatomaceous earth was superior to the other carrier materials tested (red brick, activated carbon, pumice). At 90% acetate removal, the carron, punitice). At 30% accutate removal, the acctate consumption rates were about 0.7 and 0.5 g/cu dm/h on ammonium acetate (acetate 5 g/cu dm) and dilute condensate media (acetate 2 g/cu dm), respectively. The corresponding dilution rates were 0.15 and 0.38/h. (Author's abstract)

USE OF BACILLUS THURINGIENSIS VAR. IS-RAELENSIS TO CONTROL THE NUISANCE FLY SYLVICOLA FENESTRALIS (ANISOPO-DIDAE) IN SEWAGE FILTER BEDS. Salford Univ. (England). Dept. of Biological Sci-

ences. R. M. Coombs, B. N. Dancer, D. H. Davies, J. Houston, and M. A. Learner. Water Research WATRAG, Vol. 25, No. 5, p 605-611, May 1991. 5 fig, 6 tab, 13 ref.

Descriptors: \*Bacillus, \*Biocontrol, \*Flies, \*Insect control, \*Microbial insecticides, \*Wastewater fa-cilities, England, Environmental effects, Filters, Life cycles, Public nuisance, Receiving waters.

The effectiveness of using the microbial insecticide Bacillus thuringiensis var. israelensis (Bti) to control the nuisance fly Sylvicola fenestralis at Rossendale Sewage Works, Lancashire, England, was investigated. Following a provisional trial in 1987, the whole Works (28 filter beds) was treated with a two-stage application of Bti in 1988; the first application in late April was separated from the second in late May by about half the length of the Sylvicola life-cycle. The Bti treatment was timed to reduce fly nuisance in June, the month when most complaints (71%) had been received. For each application, 0.16 L of the Bti preparation, containing nearly 10 billion spores/cu cm, was applied per The effectiveness of using the microbial insecticide ing nearly 10 billion spores/cu cm, was applied per square meter of bed surface. An 80 and 98% kill of Sylvicola larvae was recorded following the first

and second applications, respectively. The lower kill achieved by the first application was believed to be due to insufficient mixing of the Bit with the settled sewage prior to dosing. Nuisance caused by the flies was considerably reduced; there were no complaints from the public during June, although a few were received in late July and early August. Sewage purification efficiency was not affeted by Bti treatment. The maximum concentration of Bti spores in the Works' effluent was 70,000 spores/cu cm. This concentration did not appear to affect the already impoverished macroinvertebrate fauna of the receiving river. (Author's abstract)

DYNAMIC SIMULATION OF STORM TANKS. Laval Univ., Quebec. Dept. of Civil Engineering. P. Lessard, and M. B. Beck.

Water Research WATRAG, Vol. 25, No. 4, p 375-391, April 1991. 13 fig, 3 tab, 38 ref.

Descriptors: \*Combined sewer overflows, \*Model studies, \*Retention tanks, \*Simulation analysis, \*Storm-overflow sewers, \*Urban runoff, \*Water pollution control, Ammonium, Nitrogen, Precipitation, Sedimentation, Storms, Suspended solids.

Storm retention tanks are used widely for regulating pollution caused by combined sewer overflows, a notably transient, dynamic phenomenon. Nevertheless, few dynamic models of the process have hitherto been proposed. A conceptual model for simulation of the dynamic performance of a storm tank is presented. Four modes of behavior are identified: fill, draw, dynamic sedimentation and quiescent settling. Discussion is given of the problems associated with the model, in particular the characterization of spatial non-uniformities in pollutant concentrations. Simulation results are resented for the application of the model to a test storm disturbance based on field data taken from the Norwich Sewage Works in eastern England. The disturbance comprises the response of a sewer The disturbance comprises the response of a sewer network to a high-intensity, short-duration precipi-tation event, with a significant transient increase in suspended solids concentration and a transient de-pression in ammonium-N concentration. The impact of the storm tank returns on primary clarifi-er performance is found to be almost negligible. uthor's abstract) W91-10928

INFLUENCE OF REACTOR MIXING CHARACTERISTICS ON THE RATE OF NITRIFICATION IN THE ACTIVATED SLUDGE PROC-

Leeds Univ. (England). Dept. of Civil Engineer-

A. A. Azimi, and N. J. Horan. Water Research WATRAG, Vol. 25, No. 4, p 419-423, April 1991. 6 fig, 2 tab, 19 ref.

Descriptors: \*Activated sludge process, \*Mixing, \*Nitrification, \*Plug flow, \*Wastewater reactors, \*Wastewater treatment, Ammonia, Bulking sludge, Inhibition, Kinetics, Nitrogen fixing bacteria, Sedi-

The effect of longitudinal mixing on nitrification was evaluated in two bench scale activated sludge was evaluated in two bench scale activated sludge reactors of equal volume, one approximating com-plete mixing, and one approximating plug-flow mixing. The onset of nitrification was more rapid under plugflow conditions and a higher rate con-stant for nitrification wa observed. Both the num-bers and species of nitrifying bacteria were the same in both reactors and thus did not contribute to the observed differences. Lower reaction rates in the complete mix reactor were shown to result in the conserved anterences. Lower reaction rates in the complete mix reactor were shown to result from high concentration of free ammonia in the mixed liquor, which gave rise to inhibition of nitrifying bacteria. Over an extended operating period, the plug-flow reactor produced a sludge which demonstrated superior settling properties to that of the complete mix reactor. In addition incidences of shudge hulting were about whereas they were a sludge bulking were absent, whereas they were a regular feature of he complete mix system. (Auor's abstract) W91-10932

COMPARATIVE STUDY AND MATHEMATI-CAL MODELING OF TEMPERATURE, LIGHT AND GROWTH OF THREE MICROALGAE POTENTIALLY USEFUL FOR WASTEWATER

Laval Univ., Quebec. Groupe de Recherche en Recyclage Biologique et Aquiculture. P. Talbot, J. M. Thebault, A. Dauta, and J. de La

Water Research WATRAG, Vol. 25, No. 4, p 465-472, April 1991. 4 fig, 2 tab, 35 ref.

Descriptors: \*Algae, \*Growth, \*Light effects, \*Model studies, \*Temperature, \*Wastewater treatment, Biological wastewater treatment, Comparison studies, Culturing techniques, Kinetics, Mathematical studies, Wastewater management.

Since it is difficult to study potential new microal-gal candidates under all conditions of light and temperature, mathematical modeling of these variables provides a useful tool for growth prediction and characterization. Using growth rate data obtained for light intensities from 3 to 650 microE/sq-m s, and for temperatures from 5 to 35 C, the effects of these two variables on the growth of Ankistrodesmus falcatus, Phormidium bohneri and Oscillatoria agardhii have been compared and mathematically formulated. At temperatures of 20 C or less, A. falcatus showed the best growth; no significant difference existed between P. bohneri and A. falcatus at 25 C. At 30 and 35 C, P. bohneri tetter withstood high light intensities. The effect and A. falcatus at 25 C. At 20 and 35 C. P. bonnen better withstood high light intensities. The effect of light intensity on growth at the various tempera-tures tested was modeled simultaneously to express growth as a first step towards a model for the management and optimization of intensive algal cultures for the biotreatment of wastewaters. The combined treatment requirements for a high strength phenolic wastewater were examined in semicontinuous methogenic cultures. Selective pH adjustment of H-coal wastewater followed by disopropyl ether extraction was used to control the phenolic concentration fed to the serum bottle cultures. This pretrainment did not comprisely. phenolic concentration fed to the serum bottle cultures. This pretreatment did not completely remove the unidentified inhibitory compound(s) from the wastewater. Thus the addition of activated carbon to the cultures and a reduced feed rate were required to stabilize their activity. However, by the end of the 250-day test period, the cultures were maintained with a 12.5-day hydraulic retention time and were fed approximately 9 parts pH 9-extracted H-coal wastewater and 1 part inorganic nutrient solution. The influent phenol concentration was near 900 mg/L, whereas the effluent concentration was c 2 mg/L. Residual dissolved diisopropyl ether did not inhibit the anaerobic process nor was it biodegraded to methane. (Author's abstract) thor's abstract) W91-10939

EVAPORATIVE DRYING OF DREDGED MA-TERIAL.

Hole, Montes and Associates, Inc., Naples, FL. R. E. Benson, and B. L. Sill.

Journal of Waterway, Port, Coastal and Ocean Engineering (ASCE) JWPED5, Vol. 117, No. 3, p 216-234, May/June 1991. 10 fig, 5 tab, 9 ref, 5

### **Group 5D—Waste Treatment Processes**

Descriptors: \*Dredging wastes, \*Forced drying, \*Solid waste disposal, \*Spoil disposal, \*Waste management, \*Waste treatment, Evaporation, Evaporation rate, Moisture index.

Material that is dredged from U.S. harbors and rivers must be disposed of in an environmentally acceptable manner. Dredged material disposed in confinement-type disposal areas undergoes volume reduction through the processes of sedimentation, self-weight consolidation, and evaporative drying. An approximate, closed-form solution to the equation governing the evaporative drying of dredged material has been developed. This solution includes both the constant-rate and the falling-rate drying periods. Different solutions are obtained for two basic geometric cases of 'semi-infinite' and 'thin' material layers, and the analysis provides a definition to differentiate these two cases. The solutions were compared with laboratory drying tests of actual dredge spoil from Charleston Harbor, South Carolina, and show good agreement. Finally, the solutions were compared with drying tests of other researchers for material from Toledo (Ohio), Mobile (Alabama), Philadelphia (Pennsylvania), and Norfolk (Virginia). It was found that the drying of dredged material layers is at a rate much less than the evaporation potential. Freshwater materials have ligher values for moisture diffusivity than saltwater materials, and fine-grained materials have lower values for moisture diffusivity than saltwater materials, and fine-grained materials have lower values for moisture diffusivity than saltwater materials. The closed-form solution performed better in all cases than the use of pan evaporation to predict drying rates. This approach has advantages in that the degree of drying can be computed directly, without having to rely on a numerical solution (beginning at time zero) to obtain intermediate values of drying. Report No. EPA/600/D-89/124, 1989. 27p, 5 fig, 9 tab. 29 ref.

Descriptors: \*Activated sludge process, \*Powdered activated carbon, \*Regeneration, Activated carbon, Ash, Carbon, Costs, Design standards, Pollutant load, Sludge solids, Wastewater facilities.

The addition of powdered activated carbon (PAC) to activated sludge systems is a proven method of wastewater treatment. Of eleven publicly owned treatment works (POTWs) in the United States that were designed for PAC use, ten included wet air regeneration (WAR) for the destruction of secondary sludge solids and recovery of spent PAC. The eleventh plant was designed for PAC use on a single pass basis as have essentially all of the industrial facilities using this technology. Follow-ups at these facilities using this technology. Follow-ups at these facilities indicated the recurrence of certain performance and operation and maintenance (O and M) problems. As a consequence, US EPA collections and evaluations were continued through mid-1988. As part of this evaluation, all 11 POTWs were contacted to obtain basic design, O and M and performance data. The technology factors that were evaluated included effluent quality, ash buildup, carbon losses, carbon analytical methodology, wet air regeneration, recycle loadings, operational/design modifications and costs. Assumptions that PAC losses through WAR are 5% or less are based on the selected use of the nitric acid digestion technique. The measured losses reported in this study average 30% to 40% per cycle, but this is only a qualitative estimate. Ash accumulated in all PAC/WAR systems which relied on WAR blowdown for removal of a concentrated ash stream. All facilities have or are in the process of modifying the design and/or operation of their facilities to limit ash buildup. Loadings attributed to the WAR return stream are significant in terms of BOD and NH3-N. Total

phosphorus can also be quite high especially where mineral addition is used for phosphorus removal. Average 1986 O and M costs for three facilities were \$21.86, \$27.68 and \$42.00 per 1,000 gallons processed through the WAR reactor. (Lantz-PTT) W91-11099

A survey of sewage sludge treatment and disposal practices in the Member States of the European Community (EC) has been undertaken by the UK Water Research Centre between October 1985 and August 1986. The data were collected through the use of a questionnaire and the assistance of representatives from each Member State who were identified through the COST 681 program on the Treatment and Use of Organic Sludges and Agricultural Wastes. The questionnaire returns show that in 1984, 5,564,000 tons of sludge (as dry solids) were disposed of from over 32,000 sewage treatment works in the EC, excluding Portugal (for which no data are as yet available). Thirty-seven percent was recycled to land, including agriculture, land reclamation, horticulture, forestry, and parkland; 44% disposed of to landfill sites; 9% incinerated; 7% disposed of to a number of minor outlets including sacrificial land, sludge farms and processed products. Seventy-nine percent of the sludge was treated prior to disposal with the main treatments being mesophilic anaerobic digestion and cold aerobic digestion, and 71% of the sludge was dewatered, mainly by plate-pressing, belipressing, dewatering by centrifugation, and airdrying on beds. All countries forese increases in their rate of sludge production in the next ten years, with the EC's total sludge disposal in 1994 predicted to be 33% higher than that in 1984. PHYSICAL AND CHEMICAL CHARACTER-IZATION OF SEWAGE SLUDGE.

Institut de Recherches Hydrologiques, Nancy (France).

F. Colin, R. Leschber, and G. Mininni.

In: Sewage Sludge Treatment and Use: New Developments, Technological Aspects and Environmental Effects. Elsevier Science Publishing Co., New York. 1989. p 40-52. 3 fig. 1 tab. 34 ref.

Descriptors: \*Landfills, \*Sludge, \*Sludge disposal, \*Sludge treatment, \*Waste disposal, \*Wastewater treatment, Biological properties, Chemical properties, Digested sludge, Heavy metals, Physical properties, Sampling, Sludge drying, Sludge thickening, Total solids.

Sewage sludges exhibit wide variations in their physical, chemical and biological properties according to their origin, type, previous treatment and period of storage. Sampling can be considered the first step in sludge characterization. Various parameters important in sludge characterization include gravity thickening, digestibility, dewaterability, and thermal properties. Methods for determining total solids residue (dry matter) and for digestion with concentrated acids as a prerequisite for the analysis of heavy metals are available. Dewa-

tered sludge water content is not sufficient to forecast mechanical properties of the material which determine the choice of the handling devices and the behavior of the waste in a landfill. (See also W91-11115) (Brunone-PTT) W91-11115

SLUDGE REDUCTION POSSIBILITIES AS DEMONSTRATED BY THE CHEMOLYSIS PROCESS DOW STADE GMBH.

Wasserwirtschaft Stade (Germany, F.R.). H. Reincke.

H. Reincae.

IN: Sewage Sludge Treatment and Use: New Developments, Technological Aspects and Environmental Effects. Elsevier Science Publishing Co., New York. 1989. p 53-57. l fig.

Descriptors: \*Chemical treatment, \*Sludge, \*Sludge drying, \*Sludge treatment, \*Wastewater treatment, Hydrochloric acid, Hydrogen ion concentration, Residence time, Sludge filters, Sludge thickening, Steam. Thermal properties.

The Chemical Concern Dow Stade GmbH reduces excess biox sludge using the chemolysis process, which results in a reduction of greater than 80% of total sludge volume and also reduces the amount of water in the remaining filter cake (thereby improving its disposal characteristics). In October 1988, a large test plant with 200 cubic m/day of sludge from Stade City treatment plant was operated for a time period of approximately one week. In the chemolysis operation, the excess sludge is pretreated with a 10% solution of hydrochloric acid and then thickened in a concentrator. After an additional dosing of hydrochloric acid and steam to bring about the correct pH and temperature, the sludge is fed into the pipe loop reactor with a residence time of about two hours. The settled sludge is dehydrated to a 50% dry substance state in a filter press and sent to an external disposal site. Based on test runs using municipal sludge and a two-year operation of a full-sized plant, the process is suitable for the community as well as in industry for fundamental alleviation of pressing waste disposal problems. ODOUR PROBLEMS WITH SEWAGE SLUDGE.

Instituut voor Mechanisatie, Arbeid en Gebouwen, Wageningen (Netherlands).

J. H. Voorburg, and J. J. van den Berg. IN: Sewage Sludge Treatment and Use: New Developments, Technological Aspects and Environmental Effects. Elsevier Science Publishing Co., New York. 1989. p 102-115. 5 fig, 1 tab, 16 ref.

Descriptors: \*Hydrogen sulfide, \*Odor control, \*Odors, \*Sludge, \*Sludge treatment, \*The Netherlands, \*Wastewater treatment, Air pollution, Biofilters, Biological treatment, Chemical properties, Emission control, Regulations.

In the framework of the COST 681 programme, the desirability of harmonizing olfactoric measurement of odors from manure and sewage sludge has resulted in recommendations on this type of measurement. In the Netherlands, a preliminary limit for odor nuisance is expressed in odor units. However, in practice, odor emission from sewage plants is expressed in kilograms of hydrogen sulfide or ammonium. Although the calculation of odor concentrations from concentrations from concentrations of hydrogen sulfide emission reduces the number of complaints of odor nuisance. The application of chemical or olfactoric odor measurement, therefore, demands further consideration. The most effective control of hydrogen sulfide emissions from sewage plants is treatment of the air in a biofilter. Practical experience has shown that this control results in considerable odor reduction though few measurements are available to confirm this hypothesis. (See also W91-11115) (Author's abstract)

MODERN SLUDGE MANAGEMENT: THE MANAGER'S CHOICE.

MANAGER'S CHOICE.

European Water Pollution Control Association,
Markt 1, D-5205, Sankt Augustin,,G Germany.
P. J. Matthews, and W. Schenkel.
IN: Sewage Sludge Treatment and Use: New Developments, Technological Aspects and Environmental Effects. Elsevier Science Publishing Co.,
New York. 1989. p 116-128. 2 tab, 22 ref.

Descriptors: \*Europe, \*Sludge disposal, \*Sludge treatment, \*Sludge utilization, \*Wastewater treatment, Economic aspects, Governmental interrelations, Incineration, Land reclamation, Landfills, Policy making, Public participation.

The increase in sewage treatment in western Europe has created more sludge for disposal. This increase has attracted public and political attention, but managers have to take daily responsibility for the actual practice of disposal. Nevertheless, regional and national policies and laws influence the freedom of choice of managers. In simple terms managers must dispose of sludge in environmentally self-legal ways which increase maintained. managers must dispose of sludge in environmentally safe, legal ways which incur minimum costs.
Sludge disposal options include agricultural utilization, waste disposal sites in landfill, land reclamation, incineration, and marine disposal. Utilization
of wastes is often tied to marketing. The rise in unit
costs and mass of sludge for disposal will mean
that the sums expended on treatment and disposal
will become substantial business for disposers,
equipment suppliers, contractors and farmers. The
problems facing managers vary widely from counequipment suppliers, contractors and farmers. The problems facing managers vary widely from coun-try to country, but sludge disposal is always a challenge. (See also W91-11115) (Brunone-PTT) W91-11122

REMOVAL OF HEAVY METALS FROM SEWAGE SLUDGE: STATE OF THE ART AND PERSPECTIVES.

Hoofdgroep Maatschappelijke Technologie TNO, Apeldoorn (Netherlands). W. H. Rulkens, F. van Voorneburg, and J.

JUZIASSE.

IN: Sewage Sludge Treatment and Use: New Developments, Technological Aspects and Environmental Effects. Elsevier Science Publishing Co., New York. 1989. p 145-159. 1 fig, 5 tab, 26 ref.

Descriptors: \*Cost analysis, \*Heavy metals, \*Land disposal, \*Sludge treatment, \*Waste treatment, \*Wastewater treatment, Biological treatment, Chemical treatment, Comparison studies, Economic aspects, Microorganisms, Sludge drying.

Land application of sewage sludge is increasingly limited due to the presence of heavy metals. Based on data from literature and on laboratory-scale experimental research, technical and economic imexperimental research, technical and economic improvement of sludge quality is made possible by removing a substantial part of these heavy metals from the sludge. The principal methods to serve this purpose are extraction with inorganic acids, with complexing agents, or with microorganisms of the genus Thiobacillus. Generally, with these methods removal of 70% to 100% of the heavy metals is possible. In order obtain high removal percentages rather extreme conditions often have percentages rainter extenie conditions often have to be applied. Due to these extreme conditions, treatment costs are relatively high. Consequently, none of the methods is presently applied at a practical scale. A rough cost estimate indicates that the treatment costs amount to about Dfl. 300 to office of the control of the control of the control of the control of a polication of a process, a two-fold cost reduction as probably essential. Potential methods for cost reduction are decrease of treatment time, higher reduction are usercase of uncannent unit, inguier initial dry solids concentration, or reuse of extracting agent. Experimental research is necessary to verify the feasibility of these cost reduction methods. (See also W91-11115) (Author's abstract) W91-11124

IMPROVEMENT OF THE QUALITY OF SEWAGE SLUDGE: MICROBIOLOGICAL AS-

Hohenheim Univ., Stuttgart (Germany, F.R.). Inst. fuer Tiermedizin und Tierhygiene.

D. Strauch. IN: Sewage Sludge Treatment and Use: New Developments, Technological Aspects and Environ-mental Effects. Elsevier Science Publishing Co., New York. 1989. p 160-179. 12 tab, 6 ref.

Descriptors: \*Disinfection, \*Human pathogens, \*Microorganisms, \*Sludge treatment, \*Waste treatment, \*Wastewater treatment, Aerobic digestion, Anaerobic digestion, Bacteria, Bioindicators, Composting, Hydrogen ion concentration, Temperature, Viruses.

For the improvement of the microbiological quality of sewage sludge only disinfection methods can be recommended which inactivate pathogenic agents like bacteria, viruses and parasite ova. In a comprehensive study, raw and treated sludges from conventional sewage treatment plants were microbiologically investigated for potential indicator organisms. Selected indicators were tested for mperature and pH resistance. Finally, dis fected sludges from eight sewage treatment plants with different installations for sludge disinfection were microbiologically analyzed to control the effectiveness of the disinfection systems. Based on effectiveness of the disinfection systems. Based on the results of these microbiological studies, param-eters for the hygienic evaluation of disinfection methods were elaborated from a working group as well as proposals for definitions of process descrip-tion and control for pasteurization, aerobic-ther-mophilic stabilization (ATS), ATS with subsequent respectively disestions. anaerobic mesophilic digestion, treatment with Ca(OH)2, composting in windrows and in-vessel-composting (reactors). Volume reduction, and in particular ballast-water extraction, are a central feature in the sewage sludge disposal process, irrespective of the operational procedures employed. An important requirement in sludge dumping is that, whenever possible, only original sludge constituents and not additional ballast substances of an inorganic nature should be allowed to take up the finite dumping space available. For the purpose of ensuring energy-independent sewage incineration, the original dry mass of the sludges needs to be enriched to dry matter levels of between 30% and 35%. To achieve this objective, high-pressure dewatering units, such as chamber filter presses, continuous dry matter levels of between 30% and 35%. To achieve this objective, high-pressure dewatering units, such as chamber filter presses, continuous high-pressure (CHP) filter presses, or centripresses must be used. In the event of conditioning with organic flocculating adjuvants, several different dewatering units can be used. The price of increased dewatering efficiency will be increased energy consumption, longer pressing times and/or increased flocculating agent consumption. (See also W91-11115) (Brunone-PTT)

SLUDGE DEWATERING TECHNOLOGY IN PERSPECTIVE

The dewatering of sludges is an unavoidable but The dewatering of sludges is an unavoidable but very important step to solve environmental problems of sewage plants. The cost of sludge disposal can only be reduced effectively if the quantity of dumped substances is minimized. Both Centripress and HI-COMPACT, two processes developed with a future perspective to achieve maximum mechanical dewatering of sludges can be very important. Centripress is an improved version of the conventional decanter in which, by using a squeeze-press effect, the dewatering result of the the conventional decanter in which, by using a squeeze-press effect, the dewatering result of the cake can be improved by about 5% to 10% dry weight. In comparison, HI-COMPACT is a completely new process for the mechanical dewatering of sludge using pressure. In this process, a drainage system is effectively introduced into a filter compact to enforce an optimum dewatering of the sludge. Compared to conventional processes, about 60% of the residual water can be pressed out of the filter compact. Solid substances in the range of 55 to 65 mass-% can easily be achieved by this process. Because of considerable reduction in quantities of disposable substances, both processes can be economically employed to solve today's increasing economically employed to solve today's increasing disposal problems. Sewage sludge incineration can be considered as a valid alternative when other ways of disposal are not applicable, due to the presence of noxious substances (agricultural use) and lack of suitable sites (landfill). Moreover, technological improve-ments allow a safe, efficient and cheap operation to be obtained. The types of equipment most widely used are the multiple hearth and fluidized bed furnaces. Multiple hearth furnaces require less auxiliary fuel, in absence of after-burning; fluidized iliary fuel, in absence of after-burning; illudized bed furnaces provide more flexibility in operation and a more efficient combustion, even with low excess air. Main pollution problems arise from gaseous emissions and ash disposal. Particulates can be efficiently removed by either wet systems or dry ones, sulfur dioxide and hydrochloric acid controlled by scrubbers, and emissions of odors and organic compounds reduced by after-burning. and organic compounds reduced by after-burning; catalytic reduction is the only technique able to remove NOx. Ash is commonly landfilled; the leachate contamination seems to be generally comparable with that of municipal refuse landfill and is paraote with that of municipal tetuse inautin and strongly affected by chemicals used during sludge treatment with the exception of cadmium, iron and aluminum salts cause the highests leachability of trace metals. Descriptors: \*Incineration, \*Sludge disposal, \*Sludge treatment, \*Wastewater treatment, Energy conservation, Sludge conditioning, Sludge drying, Steam, Sulfuric acid

For municipalities and industries, sewage sludge from biological wastewater purification plants is becoming an increasingly large disposal problem. Fluidized bed furnaces with subsequent waste heat boilers and air preheaters have gained general acceptance because of their operating safety and simplicity. Temperatures above 700 C are adequate for certain ignition of sewage sludge. Because of SO3 formation during incineration, sulphuric acid dew points of 130 to 150 C must be expected. The degree of dewatering of the sewage sludge is the key to the utilization of energy from sludge incineration. The energy contained in the dry sludge is usually not enough to permit independent combustion at temperatures of 950 C. The amount of steam that can be produced per ton of dry sludge can be estimated as a function of water load, air pre-heating and conditioning. With decreasing water load, the specific flue gas volume rises. Predrying of the sewage sludge with steam from incineration waste heat energy recycling allows a fur-For municipalities and industries, sewage sludge eration waste heat energy recycling allows a fur-ther reduction in installation size compared with conventional fluidized bed incineration. In terms of minimum plant size and minimum additional fuel requirements, heat disposal of sewage sludge by fluidized bed incineration with utilization of the waste heat and use of the steam produced to predry the sludge is the optimum solution. The conventional fluidized bed method is often preferred, especially when the steam produced can be usefully employed for network steam, power or electricity, and district heating. Aerobic thermophilic sludge treatment (ATST) from sewage plants is an efficient process for hygienization and stabilization in large-scale and small-scale second stage procedures. However, reaching economical and reliable operation over the entire year cycle is difficult. Problems include the entire year cycle is difficult. Problems include definitions of objectives for process optimization up to control strategies and the integration of ATST into complete concepts for sewage plants. Careful planning of strategies for ATST consists basically of the selection of appropriate process objectives yielding a product suitable for further use or safe deposition. Temperature plays a central role in ATST. Thermophilic bacteria appear most suitable for application in ATST plants, due to their particular metabolic properties. They are widespread in nature and accumulate in sludge from sewage treatment plants. Their elevated metabolic kinetics lead to temperature increases suitaabolic kinetics lead to temperature increases suita-ble for thermal hygienization of the final product. Preliminary results with ATST are most encourag-ing. Experimentation will provide a sound basis for future optimization of the 880 sewage treatment plants presently operated in Switzerland. ### INFLUENCES ON THE MECHANICAL PROP-ERTIES OF SEWAGE SLUDGE FOR DISPOS-AL TO LANDFILL.

Ruhr Univ., Bochum (Germany, F.R.). Lehrstuhl fuer Wasserwirtschaft und Umwelttechnik II. R. Otto-Witte.

R. Otto-Witte. IN: Sewage Sludge Treatment and Use: New Developments, Technological Aspects and Environmental Effects. Elsevier Science Publishing Co, New York. 1989. p 307-324. 17 fig. 1 tab, 8 ref.

Descriptors: \*Sludge disposal, \*Sludge treatment, \*Sludge utilization, \*Wastewater treatment, Drain-age, Mechanical properties, Sludge drying, Sludge filters, Total solids.

The most significant property of sludges to be landfill disposed is not that of dry solid matter, but their shearing strength. A shearing strength higher than 15 to 20 kN/sq m, which is the minimum strength, determined by the minimum working value, could not normally be reached by dewatering with belt filter presses or centrifuges, even where the parameters of the machine had been optimized. Adding quicklime before or after mechanical dewatering increases the shearing strength. Three types of laboratory apparatus were tested: vane apparatus for measuring the vane tested: vane apparatus for measuring the vane shear strength, fall-cone apparatus for measuring the cone shear strength, and pressure device for

measuring bearing capacity. Higher proportions of combined drainage bring higher sludge strengths regardless of the type of dewatering. When dewatering with conventional filter presses a slight negative influence of increased solids contents was seen in the input on the final solids content, while the influence on the mechanical properties of the sludge was indetermined. Sludges dewatered with the mittence on the mechanical properties of the sludge was indeterminate. Sludges dewatered with belt filter presses and centrifuges using only polyelectrolytes for conditioning do not generally attain the vane shear strength of 15 to 20 nM/sq m, without subsequent treatment. Six water authorities have been created in France to combat water pollution and improve management of available resources: Artois-Picardy, Adour-Garonne, Loire-Brittany, Rhine-Meuse, Rhone-Mediterranean-Corsica, and Siene-Normandy. The six authorities have championed, in their respective catchment areas, the introduction of satisfactory sludge treatment and disposal methods, which include those intended for use in agriculture. The sludge treatment problem has been targeted since the authorities launched their first programs in the early 1970's, but the municipalities could not make maior progress in treating Six water authorities have been created in France grams in the early 1970's, out the minicipanties could not make major progress in treating wastewater as long as the operators were unable to draw off and treat sludge at regular intervals and dispose of it in an environmentally safe place. While significant results have been obtained over a ten-year period, much remains to be done with regard to improved treatment plants, spreading machinery, sludge and soil analysis, record keeping, etc. (See also W91-11115) (none-PTT) W91-11138

#### EXAMPLES OF AGRICULTURAL USE OF RE-SIDUAL SLUDGE.

R. Delauzanne, and J. M. Merillot.

Successful use of sewage sludge in agriculture depends on coordinated organization of sludge production, processing and spreading. The town of Cholet has a sewage works with a nominal capacity of 120,000 population equivalent (pe) (biological filters). The sludge is thickened, methanated, hen dewatered on belt filter presses and conditioned with polymers. Sludge production in 1985 amounted to 600 tons of dry matter, which was applied to fields used for the cultivation of maize and rye grass. The municipal technical services keep comprehensive records for efficient management of the system, information meetings are held twice or three times a year, and agronomic moni-

### Waste Treatment Processes—Group 5D

toring of sludge quality. The Bailleul local authority consortium runs a sewage plant with a capacity of 100,000 pe, the loading rate of which varies between 40 and 100%. The 650 tons of sludge dry matter produced annually are dewatered by centrifuging and stabilized with quicklime. The sludge is applied to silt and clay soils, used for production of potatoes, beets, maize, cereals, and pastureland. Farmers are responsible for transport and spreadrarmers are responsible for transport and spreading. Agronomic monitoring is carried out by the Nord Chamber of Agriculture. In both cases, the activities have been designed to respond specifically to the choice of agricultural use of sludge and its constraints. The storage and dewatering units provide the required flexibility, both in respect of the sewage plant/collection station interface and of sludge utilization by farmers. Descriptors: \*Sludge disposal, \*Sludge drying, \*Sludge treatment, \*The Netherlands, \*Wastewater treatment, Land disposal, Landfills, Sludge thickening.

In Rotterdam, three new wastewater treatment plants have been built during the last few years. The disposal of the large quantity of sludge is a major problem in this urban and industrial area. At the Hartelmond site dewatered sewage sludge is dried before dumping in a single sludge landfill. The natural drying process in the period April to September is improved by mechanical turning 2 to 3 times a week. In a period of 4 to 8 weeks, the 3 times a week. In a period of 4 to 8 weeks, the shear strength measured by a vane tester increases from 2.5 kN/sq nto 10 to 20 kN/sq nt (from 17 to 18% ds to 30 to 35% ds). At the Hartelmond landfill 10 kN/sq m is used as a limit for the acceptance of the sludge. Then the sludge is solid enough for dumping in a single sludge landfill. lations, Temperature.

About 50 million cubic m raw sludge are produced per year in the nearly 10,000 sewage treatment plants of West Germany. The legal prescriptions for its treatment and disposal have become increasingly strict in recent years. Due to the limited dumping ground capacities, the disposal of sewage sludge, is increasingly difficult. The solution is to increase recycling of a greater volume of sewage sludge, provided that recycling is technically and economically practical and ecologically reasonable. The operating technique developed is future-oriented. The two-stage operating technique guarantees stabilization and disinfection at the same time and leads to a considerable energy profit. In an initial anaerobic stage, the sludge will be digested resulting in usable energy in the form of biogas. The primary purpose of the treatment in this first stage, anaerobic digestion, is the stabilization of the sludge. In the second stage, the sewage sludge is treated aerobically. During digestion the sludge

heats up to temperatures of more than 50 C which results in disinfection. For self-acting biological heating of the sludge that does not reach 50 C, a separate heating system must be installed in the aerobic reactor. The primary purpose of the second stage is the disinfection of sewage sludge, if required. (See also W91-11115) (Author's abstract) W91-11141

The total phosphorus load in the sewage of Switzerland decreased with the phosphorus ban from approximately 15,000 tons/year to 11,000 tons/year. At the same time, the phosphorus load in sewage sludge decreased a mere 1200 tons/year, from 7000 to 5700 tons/year. Thus, the phosphorus load discharged into the main channel by the sewerage system was reduced from 8000 to 5400 tons/year. The efficiency of phosphorus elimination in sewage plants with precipitation is still about the same (approximately 80%), whereas the efficiency has been improved in sewage plants without phosphorus precipitation from 40% to 50%. The value of sewage sludge as phosphorus fertilizer diminished insignificantly in sewage plants working without phosphorus precipitation (reduction of the average phosphorus contents from 22 to 19 P/t minimus phosphorus precipitation (reduction of the average phosphorus contents from 22 to 19 P/t DM). Sludges from sewage plants precipitating phosphorus show a much lower phosphorus content. (See also W91-11115) (Author's abstract) W91-11142

AEROBIC-THERMOPHILIC METHODS FOR DISINFECTING AND STABILIZING SLUDGE, Fuchs Gastechnik and Wassertechnik G.m.b.H.,

Mayen (Germany, F.R.).

J. Jakob, H. J. Roos, and K. Siekmann.

In accordance with the Sewage Sludge Ordinance, in Germany only hygienically pure sewage sludge may be used on green fields and fields which are used for the cultivation of field forage since January 1, 1987. The use of the autoheated thermophilic aerobic digestion method which was introduced to the market by the FUCHS Gastechnik and Wassertechnik GmBH, can guarantee both the dissipation and the necessary stabilization of the infection and the necessary stabilization of the sludge (to reduce odor). More than 35 autoheated studge (to feutee odor). More than 3 autofleated thermophilic aerobic digestion plants, employing the FUCHS system have been operating world-wide very successfully in both domestic and indu-trial sewage facilities. Extensive examinations of trial sewage facilities. Extensive examinations of installations in operation confirm the high degree of efficiency and the economy of the method. Based on experiences gained with aerobic thermophilic sudge digestion during the last few years, the aerobic thermophilic method has found further areas of application, including the aerobic (mesophilic or thermophilic) preliminary stage for the relief of existing anaerobic digestion and, if necessary, the simultaneous disinfection. Descriptors: \*Heavy metals, \*Ion exchange, \*Separation techniques, \*Sludge disposal, \*Sludge treatment, \*Wastewater treatment, Bases, Chemical properties, Chlorine, Effluents, Hydrogen ion concentration, Landfills, Mud, Sulfuric acid.

A recent development in ion-exchange technology has the potential for attacking the problem of heavy metals in sludges and muds. Ion-exchangers manufactured in the form of magnetic beads can be recovered from sludges by the magnetic drum separators which are commonly used in the mineral and coal industries. Operation of a pilot plant has shown that the ion-exchangers can be recovhas shown that the ion-exchangers can be recovered with as little as 5 ml leakage per kl of sludge. The chemistry of the proposed process has been investigated in the laboratories of CSIRO. Sludge is stirred with a small quantity of magnetic ion-exchanger, together with a small dose of chlorine, at a pH of 2.5 to 3.0 for 30 to 60 minutes. The ion-exchanger is recovered, regenerated by dilute sulfuric acid and recycled. The acid effluent is precipitated by the lime to give a small volume of hydroxide sludge which would be disposed of in controlled landfill. Possible applications of this technology to any particular sludge can readily be assessed in the laboratory using conventional ion-exchange resins. oxidation process, Oxidation, Oxygen, Separation techniques, Sludge thickening.

The quantities of sludge in the Netherlands in relation to the surplus of animal manure and the lack of space for landfilling requires other sludge treatment processes, one of which is the wet oxidatreatment processes, one of which is the wet oxidation process. The wet oxidation process is comparable in the solids reducing capacity to incineration, without the disadvantages of dewatering, flue gases and probably reusable ash. The Vertech process is an interesting example of wet oxidation: a set of tubes is drilled vertically into the ground at a length of approximately 1500 m. High pressure is obtained by the sludge column, heat is generated by the process itself after start-up and only (pure) oxygen has to be added to start the process. After separation of the ash, the off-gases and the liquid dewatering of ash takes place, gases are treated by thermal after-burning, and the liquid is biologically treated. Wet oxidation is an environmentally acceptable alternative for sewage sludge treatment. (See also W91-11115) (Author's abstract)

HEAVY METAL SPECIATION IN SEWAGE SLUDGE FOLLOWING A PHYTO-DEWATER-ING TREATMENT.

Speciation of heavy metals in sewage sludge de-pends both on source and treatment of sludge. The different metal species are affected by interactions with adsorbing surfaces of a soil which can miti-gate metal contamination and toxicity. Chemical forms of heavy metals have been investigated in sewage sludge to evaluate changes following variations in environmental conditions via phytodewaations in environmental conditions via phytodewatering. Phytodewatering is founded on the plant evapotranspiration process to remove water from sewage sludge. The process involves cultivation of fast-growing vegetables with high water requirements on a substrate constituted by the sewage sludge itself. The phytodewatering procedure represents a possible alternative to traditional drying processes of sludges. In both sludges, heavy metals in mobile chemical forms accounted for 10% to 50% of total content. Significant quantities of bioa-vailable metals extractable by EDTA were recovered, particularly for zinc and copper which were about 25% and 15%, respectively, of the total content in sewage sludge. Descriptors: \*Sludge conditioning, \*Sludge drying, \*Sludge filters, \*Sludge treatment, \*The Netherlands, \*Wastewater treatment, Incineration, Polyelectrolytes

At the municipal wastewater treatment plant in Hengelo, The Netherland, the first membrane fil-Hengelo, The Netherland, the first membrane filterpress plant for sewage sludge dewatering in the Netherlands has become operational. The plant is designed to treat 250 cubic m digested sludge, 5% dry solids, 8 hours per day. Two membrane filterpresses, each consisting of 138 chambers are the heart of the plant, designed by Witteveen+Bos Consultants, by order of the polder board Regge en Dinkel. The operational results in the first period were quite satisfactory. The sludge cake dry solids content was 40% +/-4%, while the complete process cycle (filling, dewatering, and sludge cake discharge) took only 1.25 to 1.5 hours. When future developments require drying or comsludge cake discharge) took only 1.25 to 1.3 hours. When future developments require drying or combustion of the sludge cake, sludge conditioning with polyelectrolytes may be beneficial, and is easily fit into the membrane filterpress system. Therefore, sludge dewatering in membrane filterpresses is not only a useful method for creating a sludge cake that can be dumped, but also a useful pretreatment method for sludge drying or combus-tion. Sewage sludge from wastewater treatment plants is Sewage sludge from wastewater treatment plants is a growing problem due to the lack of facilities for sludge treatment and disposal. In general, two ways to remove sewage sludge exist: recycling, and processing and dumping of the end product. Strategic studies on sludge management are especially developed to evaluate specific possibilities for the treatment and disposal of sludge for a water quality authority. These follow six phases: inventory of present and future situations, survey of methods for processing development of a cost model. ods for processing, development of a cost model for various treatment and disposal methods, eval-uation of treatment methods, development of treatment scenarios for consecutive plan periods, and conclusions and recommendations for a long-term sludge management policy and for short-term measures. In regards to the present Dutch quality standards for sewage sludge, the maintenance of land application for smaller sewage treatment ianu application for smaller sewage treatment plants is recommended. For dewatering installa-tions above approximately 5000 tons dry solids/ year scale increases will hardly diminish annual treatment costs. (See also W91-11115) (Brunone-PTT) W91-11156

PESTICIDES AND DRINKING WATER INFOR-MATION: A PERSPECTIVE FROM EPA'S NA-TIONAL PESTICIDE SURVEY.

ItoNAL PESTICIDE SURVEY.
O. Corey.
IN: Agrichemicals and Groundwater Protection:
Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 145-151.

Descriptors: \*Drinking water, \*Nonpoint pollution sources, \*Pesticides, \*Surveys, \*Water analysis, Administrative agencies, Data interpretation, Information exchange, Information systems, Information transfer, Networks, Water quality, Well

The Environmental Protection Agency's (EPA) National Pesticide Survey is a two year study of pesticide contamination in drinking water wells. Data for the Survey is being obtained by sampling 600 community water system wells and 750 private wells across the country. The Survey tests EPA sampling techniques, laboratory methods, and relationships with State agencies which are crucial to the success of the Survey. Two different EPA-funded information networks are used to reach tionships with State agencies which are crucial to the success of the Survey. Two different EPA-funded information networks are used to reach those who are concerned with the issues raised in the Survey. One is the National Pesticides Telecommunications Network (NPTN) which is funded by the EPA's Office of Pesticide Programs and operated by the Department of Preventive Medicine and Community Health of the School of Medicine and Community Health of the School of Medicine at the Texas Technical University Health Sciences Center. NPTN provides non-emergency information on product chemistry, safety precautions, health and environmental effects, clean-up, and disposal. The second network is the Safe Drinking Water Hotline which is funded by EPA's Office of Drinking Water and operated by GEO Resource Consultants. The Hotline answers questions about contaminants, drinking water standards, and the National Pesticide Survey. In addition to the two information networks, health advisory briefs will also be a result of the Survey. The sory briefs will also be a result of the Survey. The briefs identify, for each contaminant, the level of briefs identify, for each contaminant, the level of chemical concentration which is acceptable in the drinking water. The briefs will explain adverse health effects that may occur in concentrations above the acceptable health advisory level and outline options for preventive measures that can be taken to ensure the safety of the drinking water supply. RECTANGULAR CLARIFIERS SHOULD BE CONSIDERED.

Greeley and Hansen, Chicago, IL. T. E. Wilson.

Water Engineering and Management WENMD2, Vol. 138, No. 4, p 20-22, April 1991. 2 fig, 11 ref.

Descriptors: \*Clarifiers, \*Sanitary engineering, \*Wastewater treatment facilities, Biological wastewater treatment, Circular clarifiers, Comparison studies, Design criteria, Performance evaluation, Rectangular clarifiers, Suspended solids, Wastewater treatment.

In recent years the number of designers designing rectangular clarifiers has declined. This appears to be particularly true for clarifiers following some activated sludge aeration basins. It has been asserted by some that rectangular clarifiers require 25% more settling area than circular clarifiers, but the author has not found this to be the case. Another issue is depth. Experience has shown that both types of clarifier can work well at depths as shallow as 8 ft. One of the biggest advantages of rectangular clarifiers is that they require less space. It takes 79% as much space to site a rectangular clarifier as a circular clarifier with the same surface clarifier as a circular clarifier with the same surface area. Common-wall construction also saves space and construction costs for a rectangular clarifier. Operation of rectangular clarifiers is straightforward and generally does not differ significantly from circular clarifiers with scraper-type collectors. The need to replace collector chains has been a disadvantage of rectangular clarifiers in the past, but recent experience shows that replacement only once in 5 yr is needed in many cases, and the life span may increase further with the use of non-metallic chains. Effluent suspended solids concentrations below 10 mg/l are achievable surfacemetainc chains. Erituent suspended soince concentrations below 10 mg/l are achievable surface-overflow rates (SORs) up to at least 1000 gallons/ day/sq ft. Rectangular clarifiers have been added recently to large wastewater facilities in Little Rock, Philadelphia, New York, and Phoenix, but rectangular collectors are being replaced by circular collectors in Los Angeles. The future of this issue remains unclear. (See also W91-11224) (Rochester-PTT) W91-11223

CASE FOR CIRCULAR CLARIFIERS. Brown and Caldwell, Pleasant Hill, CA. D. S. Parker.

### Waste Treatment Processes—Group 5D

Water Engineering and Management WENMD2, Vol. 138, No. 4, p 23-25, April 1991. 1 fig, 2 tab, 8

Descriptors: \*Clarifiers, \*Sanitary engineering, \*Wastewater treatment facilities, Biological wastewater treatment, Circular clarifiers, Comparison studies, Design criteria, Performance evalua-tion, Rectangular clarifiers. Simulation. Rectangular vater treatment.

In the United States both circular and rectangular clarifiers have been used successfully in biological wastewater treatment applications. In the long run, however, circular clarifiers appear to be more efficient and economical. The author's firm designs a circular clarifier that is 1 to 5 ft deeper than conventional circular or rectangular tanks, allowing some added room for sludge blanket storage during peak flow events. This greater depth allows higher overflow rates before effluent clarity is threatened. The higher overflow rate capability of the circular flocculator-clarifier means that the need for tankage construction is significantly need for tankage construction is significantly lower, resulting in savings of both capital and operating costs. The hydraulic capacity of the larger circular units is higher than the typical large rectangular tank, meaning fewer sets of equipment need to be purchased, operated, and maintained. The circular flocculator-clarifier usually is more adaptable to constrained sites in urban areas beadaptable to constrained sites in urban areas be-cause circles tend to fit into odd-shaped spaces more easily than rectangles do. Given rectangular-shaped sites, circular tanks designed at peak over-flow rates of 1500 gallons/day/sq ft take up about the same amount of room as rectangular units at 1200 gallons/day/sq ft. Recent simulation studies seem to verify existing design guides with regard to clarifier depth, weir position, and allowable overflow rates for circular clarifiers. Thermophilic biological denitrification was studied in a laboratory-upflow sludge blanket reactor fed in a laboratory-upflow sludge blanket reactor fed with ethanol as a carbon and energy source. High denitrification efficiency (>98%) was obtained at an ethanol:nitrate ratio > 2 and at a hydraulic retention time (HRT) of 5 hr. The performance of the system with respect to nitrate removal was very satisfactory (>95%), even at high nitrate (235 mg NO3-N/L) and hydraulic (3 hr HRT) loading rates. A stable sludge was formed by spherical granules 1 to 3 mm in diameter with a content of 25.8 g VS/L and were almost exclusively composed of bacteria belonging to the genus Bacillus. Penta sodium dithylene triamine penta acetate (DTPA) is one of the cationic chelating agents used in the manufacture of chemithermomechaniused in the manufacture of chemithermomechanical pulp and thermomechanical pulp. DTPA is added during bleaching to bind metal ions. To ensure a consistent quality pulp, DTPA usually is added in excess, resulting in a residual amount of uncomplexed DTPA in the wastewater stream (about 100 mg/L). Residual DTPA can complex metal ions (e.g., Ni(2+), Ca(2+), Co(2+), and Mn(2+)) that are essential for the anaerobic bacterial growth and granulation. The effect of DTPA nanaerobic granular sludge biomass was examon anaerobic granular sludge biomass was exam-ined. The acetoclastic ability (capacity of the microbial culture to convert acetic acid to methane) was studied using batch anaerobic toxicity assays. Batch and continuous upflow anaerobic sludge bed filter reactor tests indicated that acidogenic and methanogenic activities were relatively unaffected methanogenic activities were relatively unaffected by short-term exposure to DTPA, but that long-term exposure to high concentrations (> 1800 mg/L) to low concentrations (180 mg/L) in the absence of a sacrificial trivalent cation eventually led to inhibition of hydrogen consuming and acetoclas-tic methanogens. An anaerobic sludge bed reactor exposed to DTPA that had been complexed to sacrificial Fe(3+) was not affected. (Rochester-PTT) W91-11277

FERTILITY OF WORKERS CHRONICALLY EXPOSED TO CHEMICALLY CONTAMINATED SEWER WASTES.
Cincinnati Univ., OH. Coll. of Medicine.
G. K. Lemasters, H. Zenick, V. Hertzberg, K. Hansen, and S. Clark.

Descriptors: \*Epidemiology, \*Fertility, \*Popula-tion exposure, \*Public health, \*Toxicity, \*Wastewater facilities, Chronic effects, Sewer sys-tems, Sublethal effects, Water pollution effects.

A study was conducted to assess fertility in males exposed to mixed industrial and domestic wastes. The workers were employed at a large metropolitan wastewater collection and treatment facility in a highly industrialized city. Eligibility requirements limited the cohort to currently employed, married men under the age of 36 at time of hire, and employed for at least one year at the participating company. A detailed reproductive history was obtained from the wives of 231 employees in order to evaluate fertility. Daily work records were used to define exposure status. To ascertain problems of infertility, the ratios of observed live births to expected live births (generated from US birth probabilities) for exposed and nonexposed groups were calculated, and the ratios of these Standardized Fertility ratios (SRFs) were compared. Other analyses considered the couples' contraceptive history and preexposure versus postexposure experience. Though multiple statistical approaches were used to examine the data, the conclusion of this study was that exposure to chemical proacties were used to examine the data, to calculate of this study was that exposure to chemical mixtures was not associated with a decrease in the couples' fertility. Ligand-modified micellar-enhanced ultrafiltration (LM-MEUF) is a membrane-based separation technique which can selectively remove specific ions from an aqueous solution containing several ions of like charge. In LM-MEUF, surfactant and ampho-philic ligand are added to the contaminated water. The surfactant forms aggregates called micelles, and the ligand is selected to complex the ion of interest and solubilize strongly in the micelles. The interest and solubilize strongly in the miceles. I are result is micelles containing a high fraction of the ligand and the target ion. If the surfactant is chosen to have the same charge as the target ion, other ions in solution with this same charge will not tons in solution with time same change. While the associate with the micelles, making the retention of ions by the micelles very selective. The solution is then passed through an ultrafiltration membrane with pore sizes small enough to block the passage of micelles. In this study, divalent copper is the target ion in a solution also containing divalent target ion in a solution also containing divalent calcium. A cationic surfactant is used with N-ndodecyl-iminodiacetic acid as the copper-specific ligand. Rejections of copper up to 99.2% are ob-served, with no rejection of calcium, showing that LM-MEUF has almost perfect selectivity, as well Loy-MELUF has almost perfect selectivity, as well as high capacity in this case. This method could be used on wastewaters containing a toxic heavy metal cation with other relatively innocuous cations, such as those produced by metal plating plants. (Author's abstract)

Waste disposal

One popular proposal for the disposal of wastewater treatment sludge is the use of the sludge for soil amendments. The potential risks associated with disposing of sludge on soil for groundwater and crop contamination by enteric groundwater and crop contamination by enteric viruses requires better understanding to reduce these risks to acceptable levels. The survival of three enteroviruses (polio 1, coxsackie B3 and echo 1) and a rotavirus (SA-11) was studied under labo-ratory conditions. The effects of temperature, dissolved oxygen, detention time, sludge source and virus type on virus inactivation were determined. Temperature was the single most important factor influencing the rate of virus inactivation. No significant differences were found for virus inactivation rates at dissolved oxygen levels between 0.9 and 5.8 mg/L. However, the inactivation rate of the viruses under aerobic conditions was significantly greater than the inactivation rate under anaerobic conditions. This suggests that different factors are influencing virus survival under aerobic and anaer-obic conditions. It is possible that components of aerobic digestion accelerate virus inactivation and/ or components of anaerobic digestion such as detergents protect viruses from inactivation. Sludge source, detention time and virus type did not significantly influence the rate of virus inactivation. (Doyle-PTT) W91-11319

MODELING THE UPFLOW ANAEROBIC SLUDGE BED-FILTER SYSTEM: A CASE WITH HYSTERESIS.

Biotechnology Research Inst., Montreal (Quebec). S. R. Guiot. Water Research WATRAG, Vol. 25, No. 3, p 251-262, March 1991. 7 fig, 4 tab, 34 ref.

Descriptors: \*Activated sludge process, \*Anaerobic digestion, \*Model studies, \*Wastewater treatment, Chemical oxygen demand, Filter media, Hydrogen ion concentration, Hysteresis, Kinetics, Mathematical models, Retention time.

A hybrid upflow sludge bed-filter (UBF) anaerobic reactor was successfully used for treatment of synthetic soluble 1% sugar waste. Anaerobic digestion of organic wastes is sequentially processed by different groups of bacteria including acidogens, acctogens and methanogens: the product of one group being the substrate for another group. However, some models validate digestion as a single one population system. The acetoclastic methanogenipopulation system. The accroclastic methanogemiss is the rate limiting step, in balanced anaerobic digestion of carbohydrates. Using mass balances around the system, a UBF system under constant operational conditions can be described in statespace equations which give predictions of efficiency rates for methane production as a function of the hydraulic residence time, biomass concentration and influent concentration. An hysteresis ph nomenon was observed with respect to changes in nomenon was observed with respect to changes in acidogenic/acetoclastic specific activities ratio. The Haldane equation was adapted for predicting performance inhibition by undissociated volatile fatty acids as a function of substrate-COD and pH. The Monod and adapted Haldane models were solved simultaneously with substrate mass balance of a UBF reactor. The soluble COD removal efficiency of the property of the control of ciency and methane productivity were predicted as a function of the dilution rate. Critical values of solid and hydraulic residence times were also esti-mated. (Doyle-PTT) W91-11321

COLOUR REMOVAL FROM TEXTILE EF-FLUENTS BY ADSORPTION TECHNIQUES. Minya Univ. (Egypt). Dept. of Chemical Engi-

M. S. El-Geundi. Water Research WATRAG, Vol. 25, No. 3, p 271-

273, March 1991, 4 fig. 2 tab. 4 ref.

Descriptors: \*Adsorption, \*Color removal, \*Dye industry wastes, \*Industrial wastewater, industry wastes, \*Industrial wastewater, \*Wastewater treatment, Adsorbents, Adsorption kinetics, Corn, Egypt, Textile mill wastes.

The treatment of aqueous effluents in countries in the Middle and Far East is extremely important as an means of conserving and recycling water. The rapidly growing textile industries in these areas produce large quantities of effluent, but conventional adsorption systems which use activated carbon are expensive and require regeneration. In Egypt, a vast amount of maize cob is available as an agricultural waste. The maize cob plus adsorbed dye could be burned as much of it is used as a fuel already. The adsorption of two basic dyestuffs (Astrazon Blue and Maxilon Red) and two acid dyestuffs (Telon Blue and Erionyl Red) into maize dyestuffs (1eion Blue and Erionyl Red) into mazze cob was studied. High adsorptive capacities were observed for the adsorption of the basic dyestuffs, namely 160 and 94.5 mg dye per g maize cob for Astrazon Blue and Maxilon Red, respectively. Lower capacities were obtained with the acid dyestuffs, namely 47.7 and 41.4 mg per g maize cob for Erionyl Red and Telon Blue, respectively. The structure of the maize cob is cellulose based, and the surface of cellulose in contact with water is negatively charged. Thus acidic dyes suffer a coulombic repulsion due to the presence of anionic groups in maize cob structure. Basic dyes, on the other hand, are attracted approaching the maize cob structure. A series of contact-time experiments was undertaken in an agitated batch absorber to assess the effect of the system variables, namely, agitation speed, maize cob particle size and maize cob mass. The data show that increasing the rate of agitation and the mass of maize cob increases the rate of dye adsorption, while increasing the parti-cle size decreases adsorption rate. (Doyle-PTT)

1-NAPHTHALENESULFONIC ACID AND SUL-1-NAPHTHALENESULFUNIC ACID AND SULFATE AS SULFUR SOURCES FOR THE GREEN ALGA SCENEDESMUS OBLIQUUS. Kernforschungsanlage Juelich G.m.b.H. (Germany, F.R.). Inst. füer Biotechnologie. M. Luther, and C. J. Soeder. Water Research WATRAG, Vol. 25, No. 3, p 299-307, March 1991. 11 fig. 5 tab, 38 ref.

Descriptors: \*Algae, \*Biological wastewater treat-ment, \*Detergents, \*Dyes, \*Scenedesmus, \*Sulfur, \*Wastewater treatment, Biomass, Carbon radioiso-topes, Chlorophyta, Radioactive tracers, Water

Naphthalene sulfonic acids, manufactured as pre-products for detergents and textile dyes, have been classified as persistent xenobiotics that can pass wastewater treatment plants without significant biodegradation. It is of scientific and practical interest to find biotechnological ways to degrade these materials in the effluents of factories producing these compounds. The green alga Scenedesmus obliquus was grown in batch cultures either with sulfate or 1-naphthalenesulfonic acid (1-NS) or both compounds as sulfur source. Growth rates of the sulfur compounds were dependent on the initial concentrations of the sulfur sources (Ks-value for sulfate = 9.9 micro moles; Ks-value for 1-NS for sulfate = 9.9 micro moles; Ks-value for 1-NS = 46 micromoles). Threshold concentrations for uptake were 6.3 micromoles for sulfate and 38.2 micromoles for 1-NS. When 0.014-0.140 micromoles of sulfate were added to the medium containing 0.217 micromoles of 1-NS, the amount of 1-NS eliminated after 5 d was reduced in proportion to the sulfate dosage. The calculated sulfur elimination rates and those obtained using S-35 labeled compounds agreed with one another to a large nation rates and those obtained using 5-3 labeled compounds agreed with one another to a large extent. The carbon of C-14 labeled 1-NS did not accumulate in the biomass. When cultivating Scenedesmus obliquus with sulfate and 1-NS as sulfur sources in a turbidostat the maximum growth rate. of Scenedesmus obliquus was 1 micron/0.107 h with sulfate at a preset biomass concentration of 85 mg dm/L and a maximal elimination of about 70% mg dm/L and a maximal enimanation of about 0'w was determined at a biomass concentration of 1510 mg dm/L. Growth and elimination rate were re-duced when 1-NS elimination reached 14%. Addi-tional batch experiments showed that small

amounts of sulfate had a great influence on growth and on elimination of 1-NS. Pulse addition of sulfate to a continuous culture with 1-NS as sulfur source increased the growth rate 20 times and the elimination rate of 1-NS 15 times. (Doyle-PTT) W91-11326

FOAMING IN ACTIVATED SLUDGE PLANTS: A SURVEY IN QUEENSLAND, AUSTRALIA AND AN EVALUATION OF SOME CONTROL

Queensland Univ., Brisbane (Australia). Dept. of Microbiology.

and A. C. Hayward.
Water Research WATRAG, Vol. 25, No. 3, p 313-317, March 1991. 2 fig, 3 tab, 31 ref.

Descriptors: \*Activated sludge process, \*Foaming, \*Wastewater facilities, \*Wastewater treatment, Actinomyces, Australia, Evaluation.

Activated sludge sewage treatment plants that were affected by biological foams attributed to the presence of actinomycetes were surveyed in Queensland, Australia. Nocardia amarae and Nocardia pinensis were the predominant organisms found to accumulate selectively in the foam phase. found to accumulate selectively in the foam phase. Foaming was shown to be a significant problem in Queensland with 92% of surveyed plants being affected. A total of 60% of these plants suffered from bulking, however, no correlation between these two problems was noted. No operational, design, influent or weather feature was found to be consistent in all foaming plants. Apart from the fact that the plants were all variations of the activated sludge process, the only other aspect shared by them was that large numbers of filamentous bacteria were present in the foam. Field scale trials were occulted to evaluate control strategies bacteria were present in the foam. Field scale trials were conducted to evaluate control strategies against actinomycete foaming or scumming in activated sludge plants. The effects were assessed of altering the rate of return activated sludge recycle, dosing of the aeration tank with anaerobic digester products, the addition of a commercial product specifically designed to control foaming, altering studge age, varying levels of mixed liquor suspended solids (MLSS) and altering other operational features. These strategies did not effectively con-trol scumming in activated sludge, however, some operational features, such as location of aerators and liquid surface turbulence were highlighted as exacerbating the problem. When an explosion occurred in the Abbeystead valve house of the Lancashire Conjunctive Use Scheme causing injuries and loss of life, an inde-pendent investigation of the accident and repairs pendent investigation of the accident and repairs and modifications to the scheme were carried out. The cause of the explosion was determined to be ignition of a mixture of methane and air that had accumulated in the wet room of the valve house. The methane had been displaced from a void that had formed in the Abbeystead end of the Wyresdale tunnel during a period of 17 days before the explosion when no water was pumped through the system. When pumping of water was resumed, the

### Waste Treatment Processes—Group 5D

water level in the tunnel rose slowly and pushed out the methane and air mixture in the void through the air valves near the end of the tunnel. The void in the tunnel was produced by loss of water through a wash-out valve at the outfall, which had been left permanently cracked open to minimize silt accumulation in the dead end of the minimize silt accumulation in the dead end of the tunnel beyond the valve house. After several options were studied, the following modifications to the conjunctive scheme were selected to ensure the future safety of the facility: a new vent outlet on the main tunnel to discharge free gas before it reaches the valve house; pipework to pass any vented gas to the valve house wet room to be discharged at roof level through open vent stacks; reconstruction of the valve house with a new concrete roof over the dry room; a mesh roof over the wet room permitting free ventilation; replaceconcrete roof over the dry room; a mesh roof over the wet room permitting free ventilation; replace-ment of all other existing air valves in the wet room by open vent stacks discharging at roof level; and construction of a dry moat around the periph-ery of the valve house for safety and security purposes. In addition the wet room is to be kept free of all electrical wiring and equipment and the circulation system for the dead-end branch of the tunnel will be improved. (Geiger-PTT)

APPLICATION OF PHYSICOCHEMICAL TREATMENT TO AN OVERLOADED SEWAGE WORKS.
K. Jones, D. E. Smith, and C. Thomas.
Journal of the Institution of Water and Environmental Management JIWMEZ, Vol. 5, No. 1, p 28-35, February 1991. 10 fig, 4 tab, 9 ref.

Descriptors: \*Biological wastewater treatment, \*Physicochemical treatment, \*Wastewater treatment, Aluminum sulfate, Biochemical oxygen demand, Cost-benefit analysis, Lime, Phosphate removal, Polyelectrolytes, Sedimentation.

Two methods of physicochemical treatment were applied to a wastewater treatment works to relieve organic overloading on biological processes and improve effluent quality. The Clariflow system was retrofitted to the existing works in parallel with the two primary sedimentation tanks and provided additional sedimentation with Clarifloc EF (a lime-based slurry) and commercial alumnum suffer. An in-house system of design commercial and the provided additional sedimentation with Clarifloc EF (a lime-based slurry) and commercial aluminum sulfate. An in-house system of dosing coagulant and coagulant aid into existing tanks was tried using Zetag 92, a cationic polyacrylamide at 1 mg/L and aluminum sulfate at 400 ml product per cu m sewage (equivalent to 19.5 mg/L as A13+). Both Clariflow and straight chemical addition increased the efficiency of primary sedimentation, thereby reducing the load applied to biological filters and improving final effluent quality. The Clariflow process removed 31-65% of the BOD entering the tank, while straight chemical addition removed 26-50%. Values for suspended solids were 69-85% and 53-84%, respectively. Cost-benefit studies suggested that a chemical cost of 2-3 pounds/cu m was optimum for the Clariflow process, while about 3-5 pounds/cu m gave the best result for straight chemical addition. PH values ranging from 8.1 to 9.2 in the sewage from the Clariflow plant applied to the biological filters had no adverse effect on their performance. The Clariflow process was operated under almost constant flow conditions, while the straight chemical addition work was subject to normal diurnal flow variations. (Geiger-PTT)

# COMPARISON OF ALTERNATIVE OPERAT-ING MODES ON THE HALIFAX ACTIVATED-SUUDGE PLANT. Yorkshire Water Authority (England).

G. A. Jon

Journal of the Institution of Water and Environ-mental Management JIWMEZ, Vol. 5, No. 1, p 43-50, February 1991. 5 fig, 7 tab, 2 ref.

Descriptors: \*Activated sludge process, \*Biochemical oxygen demand, \*Wastewater treatment, Aeration, Clarification, Comparison studies, Costs, Hydraulic loading, Settling tanks, Sludge bulking.

The Halifax activated sludge wastewater treatment plants have been operated in the Halifax mode

since 1981. This mode, termed mode 2, uses all four aeration lanes and both final settling tanks and has successfully prevented previous bulking of the activated sludge. Two other operation modes were employed to study operation of the plants under stressed conditions and to improve operation costs. Mode 1 employed conventional treatment using only two of the four aeration lanes, each with a final settling tank. Mode 3 used a modified Halifax mode with a facility to allow sludge to bypass the final settling tank. Mode 1 allowed a high hydraulic loading capacity to be treated satisfactorily with the effluent quality meeting the required standards with Vitox oxygen on demand at an average rate with vitox oxygen on demand at an average rate of slightly over 1 ton/day. However, problems were encountered in containing the mixed liquor blanket within the final settling tanks for short periods at peak flows and the clarifier capacity might be inadequate to deal with the mass of solids received from the exceived ingin be madequate to deal with the mass of solids received from the aeration lanes. Operating in the Halifax mode 2 with Vitox oxygen, BOD loads averaged 2.81 tons/day compared to the rated capacity of the mechanical-aeration equipment of about 2 tons/day. The additional load required provision on demand of 0.54 tons/day Vitox provision on demand of 0.54 tons/day Vitox oxygen. By employing only half the treatment plant during mode 3 of operation it was possible to apply an average BOD load of 4.15 tons/day compared to the approximate rated capacity of 2 tons/day. The Vitox system provided, on demand, an average of 2.19 tons/day oxygen to support the mechanical equipment. An uprated works treating a 65% increase in BOD load would have an increase in cost (for oxygen and electricity) of about 100%. (Geiger-PTT)

#### LIQUID EFFLUENTS: NEW SOLUTIONS TO OLD PROBLEMS.

AEA Technology, Harwell (England). Energy and Environment

Journal of the Institution of Water and Environmental Management JIWMEZ, Vol. 5, No. 1, p 51-57, February 1991. 7 fig, 1 tab, 9 ref.

Descriptors: \*Electrochemistry, \*Filtration, \*Industrial wastes, \*Liquid wastes, \*Membrane processes, \*Separation techniques, \*Waste treatment, Dewatering, Effluents, Electrodialysis, Incineration, Ion exchange, Osmosis, Oxidation.

The nuclear industry in collaboration with industrial associations have advanced several technologies that will be useful in the future for the processing of industrial effluents. Membrane processes are finding increasing applications in the waste treatment field for the specific removal of trace compounds. Cross-flow, micro-and ultra-fil-tration can remove finely-divided colloidal materiwhile reverse osmosis can remove dissolved solids, and pervaporation can be used to recover and purify organic solvents. Electrically-enhanced and purify organic solvents. Electrically-enhanced filtration processes have been used to control fouling of membranes and maintain a high permeation rate. Electrically conductive micro-and ultra-filtration membranes have cross-flow conditions through the periodic application of short current pulses generating gas bubbles which remove the superficial fouling layer. Electro-osmotic dewatering is attractive for the stream concentrations of intermediate solids content during sludge thickening. Electrochemical processes with the potential for liquid effluent treatment include: electrically enhanced ion-exchange processes, electrochemical tor neural treatment include: electrically enhanced ion-exchange processes, electrochemical ion-exchange methods, ion-exchange/electrodialysis hybrid techniques, and Harwell electrochemical ion-exchange processes for concentrating non-ferrous metals for later recovery by conventional plating methods. Oxidation-reduction reactions find a curvature of amplications is host increasing and plating methods. Oxidation-reduction reactions find a number of applications in both inorganic and organic systems. Effective removal of toxic, electroactive species can be brought about via redox reactions at the electrode/electrolyte interface. Chemical oxidation is an alternative route to incining the destruction of organic compounds. eration for the destruction of organic compounds. Wet oxidation breaks down organic materials to carbon dioxide and water in a process analogous to incineration. Electrochemical incineration uses a highly oxidizing form of silver to effect the destruction of organic compounds in a nitric acid medium. (Geiger-PTT)

### DESIGN OF SEWAGE-TREATMENT PLANTS IN BRISBANE, AUSTRALIA.

M. L. Lever.

Journal of the Institution of Water and Environ-mental Management JIWMEZ, Vol. 5, No. 1, p 58-65, February 1991. 6 fig.

Descriptors: \*Activated sludge process, \*Advanced wastewater treatment, \*Australia, \*Nitrogen removal, \*Organic loading, \*Wastewater treatment, Aeration, Cost analysis, Design criteria, Performance evaluation, Sludge dewatering, Sludge digestion, Sludge thickening.

Brisbane City Council provides sewage-treatment facilities for a population of 800,000, together with industrial effluents having an organic loading equivalent to a further 600,000 people. Three rojects are described to illustrate some of the ifferent designs and operating parameters used in different designs and operating parameters used in Brisbane, where the sewage temperature ranges from 18 to 29 C and stormwater is collected sepa-rately. The first project is a 400,000 population equivalent augmentation to a conventional activat-ed-sludge plant located at Luggage Point. The Luggage Point plant utilizes preliminary treatment, primary treatment, an activated-sludge process, sludge thickening, and sludge digestion, drying, and dewatering under an automatic control and monitoring system. The two other plants, the monitoring system. The two other plants, the Gibson Island and the Wacol sewage treatment Ordinary and the waron sewage treatment plants have to comply, among other standards, with an effluent standard of 10 mg/L for total nitrogen. This requirement, together with site constraints and an economic evaluation of alternatives, resulted in the selection of the extended-aeration process incorporating anoxic zones and separate mixing and aeration. These contemporary designs are specific to Brisbane conditions, and are intend-ed to facilitate reliable operation while being cost effective. (Author's abstract) W91-11361

### STUDY ON TRIPLE-MEMBRANE-SEPARA-TOR (TMS) PROCESS TO TREAT AQUEOUS EFFLUENTS CONTAINING URANIUM.

Institute of Nuclear Energy Research, Lung-Tan (Taiwan).

M. L. Chu, C. P. Tung, and M. C. Shieh. Separation Science and Technology SSTEDS, Vol. 25, No. 13/15, p 1339-1348, 1990. 8 fig, 1 tab,

Descriptors: \*Filtration, \*Liquid wastes, \*Membrane processes, \*Reverse osmosis, \*Uranium. \*Wastewater treatment, Effluents, Fluorides, Microfiltration, Separation techniques, Ultrafiltration.

An effective process incorporated with the novel membrane separation technology was developed to recover uranium from the filtrate effluent of uranium dioxide conversion processes. The prominent feature of the process is that it utilizes separation reature of the process is that it utilizes separation characteristics of three different types of membranes as follow: separation of uranium species from effluent of high fluoride content by ultrafiltration membrane, separation of uranium species from effluent of low fluoride content by reverse room effluent of flow indone content by reversions osmosis membrane, precipitation of uranium species with hydrogen peroxide, and filtration of uranium bearing precipitates by microfiltration membrane. The process is simple and feasible for treatment of liquid waste containing both soluble and suspended uranium species. The recovery of urani-um can reach 95% and the treated effluents meet the current environmental standards. (Author's abstract) W91-11367

### REMOVAL OF HEAVY METALS AND OTHER CATIONS FROM WASTEWATER USING ZEO-LITES.

### Group 5D—Waste Treatment Processes

Vol. 25, No. 13/15, p 1555-1569, 1990. 3 fig, 11 tab,

Descriptors: \*Cleanup operations, \*Heavy metals, \*Mine wastes, \*Wastewater treatment, \*Zeolites, Absorption, Cation exchange, Clay minerals, Ion

Zeolites from abundant natural deposits were investigated by the Bureau of Mines for efficiently cleaning up mining industry wastewaters. Twenty-two zeolites were analyzed by X-ray diffraction and inductively coupled plasma analysis (ICP). These included clinoptilolite, mordenite, chabazite, erionite, and phillipsite. The zeolites were primari-ly in the sodium or calcium form, but potassium and magnesium counter ions were also present. Bulk densities of a sized fraction (minus 40, plus 65 mesh) varied from 0.48 to 0.93 g/ml. Heavy metal mesh) varied from 0.48 to 0.93 g/ml. Heavy metal ion exchange loading values on two clinoptilolites ranged from 1.6 milliequivalents/g for lead to 0.00 milliequivalents/g for mercury in single ion tests. The selectivity series was determined to be Pb>Cd>Cb>Cu(II)>Co(II)>Cr(III)>Zn>N (III)>Hg(II). Sodium was the most effective exchangeable ion for ion exchange of heavy metals. Wastewater from an abandoned copper mine in Nevada was used to test the effectiveness of clinetical for treating a multi-ion wastewater. Alternative for the state of the control of t optilolite for treating a multi-ion wastewater. Aluminum, Fe(III), Cu(II), and Zn in the copper mine minum, Fe(III), Cu(II), and Zn in the copper mine wastewater were removed to below drinking water standards, but Mn(II) and Ni(II) were not. Calcium and NH4 were absorbed preferentially to all heavy metals were eluted from zeolites with 3% NaCl solution. Heavy metals were concentrated in the eluates up to 30-fold relative to the waste solution. Anions were not adsorbed by the zeolites. (Au-Anions were not adsorbed by the zeolites. TREATMENT OF WASTE WATER FROM WET LIME(STONE) FLUE GAS DESULFURIZA-TION PLANTS WITH AID OF CROSSFLOW MICROFILTRATION.

Utrechtseweg 310, 6812 AR Arnhem, The Nether-

Janos.
G. D. Enoch, W. Spiering, P. Tigchelaar, J. De Niet, and J. B. Lefers. Separation Science and Technology SSTEDS, Vol. 23, No. 13/15, p 1587-1605, 1990. 9 fig, 5 tab,

Descriptors: \*Desulfurization, \*Heavy metals, \*Industrial wastes, \*Limestone, \*Microfiltration, \*Wastewater treatment, Arsenic, Cadmium, Chromium, Copper, Fouling, Lead, Membrane processes, Mercury, Nickel, Selenium, Sulfides, Zinc.

A treatment method was developed to remove heavy metals such as As, Cd, Cr, Cu, Hg, Ni, Pb, Se and Zn very efficiently from wastewater from wet limestone-gypsum flue gas desulfurization plants (FGD). This method was based on coprecipation of heavy metal bydroxides and sulfides plants (PGD). Into method was based on coprecipitation of heavy metal hydroxides and sulfides followed by crossflow microfiltration as a post-treatment. The experiments were carried out on pilot plant scale with actual wastewater from a FGD plant downstream of a coal fired boiler. The effect of membrane fouling as a function of several process parameters was investigated. From scanprocess parameters was investigated. From scaning electron microscopy-energy dispersive spectroscopy analysis it was found that the fouling layer on the membrane surface consisted mainly of gypsum and Mg., Al., Si., and Fe-compounds. Membrane fouling could be decreased by periodic backwashing and by increasing the liquid velocity in the membranes. Moreover, a computer controlled start up procedure of the crossflow microfiltration unit was developed to minimize the effect membranes fouling and to increase the operator to compute the control of membranes fouling and to increase the operator to compute the control of membranes fouling and to increase the operator to control of membranes fouling and to increase the operator to control of the control of membranes fouling and to increase the operator to control of the control nitration unit was developed to minimize the effect of membrane fouling and to increase the operating time before chemical cleaning of the membranes is necessary. The developed chemical cleaning was very successful because it was possible to achieve the initial permeate flux after each experiment. (Author's abstract)

Immobilized cell reactors may offer several advantages over free-cell systems in the treatment of hazardous and toxic wastes. Besides reducing biomass washout in continuous reactors, immobiliza-tion facilitates biomass separation from the process stream. Immobilized cells may also be more resist-ant to higher concentrations of toxic species and cell concentrations can be much higher. This last feature can result in higher efficiencies due to increased biodegradation rates per unit of reactor volume. Aerobic biodegradation was studied using activated sludge immobilized in calcium alginate gel. Hydrogen peroxide provided the dissolved oxygen source in a recirculation reactor that was oxygen source in a recirculation reactor that was operated batchwise and continuously. Responses to changes in benzene concentrations, flow rates, and biomass loadings were measured. Sixty percent of the benzene was biologically degraded in batch tests after 24 h using an initial concentration of 100 mg/L. A residence time of 17.14 h was required to biologically reduce heavener concentrations from biologically reduce benzene concentrations from 600 ppm to below the detection limit (1 ppm) during continuous operation. The system was mod-eled using Monod kinetics for substrate utilization. The apparent mg/L/h values changed with biomass loadings, but were independent of initial ben-zene concentrations. The aromatic species in BTX mixtures (i.e. benzene, toluene and o-, m-, and p-xylene) can all be degraded at the same time. (Doyle-PTT) W91-11381

ACTIVATED SLUDGE PROCESS TO REDUCE THE POLLUTION LOAD OF A DYE-INDUS-

MAN TABLE. MANAGEMENT ASSOCIATION FOR HELDRICH ASSOCIATION FOR MICROBIOLOGY. P. Kanekar, and S. Sarnaik. Environmental Pollution ENPOEK, Vol. 70, No. 1, p 27-33, 1991. 3 tab, 12 ref.

oxygen demand, Color removal, Dyes, Effluents, Feces, Nitrogen, Organic carbon, Phenols, Pseudo-monas, Sludge digestion, Water quality standards.

A laboratory-scale activated sludge process was developed to reduce the pollution load of a dye-industry waste containing aniline, phenol, methyl violet, and rhodamine B as its major components. The waste, collected from a factory near Pune (India), had an organic load of 5,576 mg/L as the chemical oxygen demand (COD) 896 mg/L as total organic carbon (TOC), and a phenol content of 31.5 mg/L. A microbial sludge capable of growing on the waste was developed from cattle dung and used as a bioinoculum for the process. This resulted in reductions of 60% in COD, 37% in TOC, and 92% in phenol content, and a decrease in optical density from an initial 0.915 to 0.360 at 580 nm. Microorganisms isolated from the sludge were identified as Pseudomonas alcaligenes and P. mendocina. Although treated effluents did not reach the standards prescribed by the Water Pollu-tion Control Board, these studies indicate the feasition Control Board, these studies indicate the feasi-bility of a microbial process to reduce the pollution load of dye-industry waste. As appropriate con-trols were run and the experimental values of reduction in COD, TOC, ammoniacal nitrogen, and phenol were estimated against control values, it became apparent that the observed reduction in organic load from the experimental set was due to microbial activity, and cannot be attributed to mere aeration or volatilization. Descriptors: \*Industrial wastewater, \*Path of pollutants, \*Pulp and paper industry, \*Pulp wastes, \*Symposium, \*Wastewater treatment, \*Water pollution control, Biodegradation, Chlorinated hydrocarbons, Environmental effects, Pollutant identification, Toxicity, Water pollution effects.

The Third International Symposium on Forest Industry Wastewaters was aimed at bringing together industrialists, scientists, authorities, consultants and contractors worldwide to introduce the latest and contractors worldwide to introduce the latest innovations in pulp and paper industry water pollution control and to discuss the environmental effects of the industry's effluents. Forty-five technical and 10 environmental papers, together with 22 posters, were presented. In the symposium special interest was focused on slowly biodegradable compounds and nutrients. The occurrence, biode-gradability and environmental effects of toxic xenobiotic and wood-derived pulp and paper industry wastewater constituents such as chlorinated phenowastewater constituents such as chlorinated phenolic compounds were of primary concern. Nutrient-balanced biological effluent treatment was examined for its relationship to the overall organic removal efficiency, operation costs, and the environment. Anaerobic treatment systems have been successful-ly applied over the last decade for combating wastewater pollution loads in the forest industry. However, anaerobic treatment of certain paper mill waste streams is limited by the presence of toxic and recalcitrant organic compounds, high concentrations of sulfur and in some cases high tewater temperatures. Anaerobic treatment is wastewater temperatures. Anaerobic realment is highly effective for waste streams composed mostly of readily biodegradable organic matter, such as thermomechanical pulping effluents and condensates. Moreover, the time is approaching rapidly in which the anaerobic treatment method is rapidly in which the anaerobic treatment method is becoming applicable to the category of difficult forest industry wastewaters. Toxic wastewaters contain large fractions of recalcitrant lignin. Dilution to subtoxic levels should be applied, as well as careful start-up procedures for the maximum adaption of anaerobic microorganisms. If this is not feasible, adsorption, precipitation or oxidation of organic toxins may be applied. Anaerobic treatment can also be applied as an essential part of an integrated treatment resource preservation system. For forest industry wastewater, sulfate and sulfite reduction during anaerobic digestion can be comror rotest industry wastewater, suitate and suffice reduction during anaerobic digestion can be combined with sulfur recovery systems. Biological recovery of elemental sulfur from hydrogen sulfide in anaerobically treated forest industry effluents has promise. The anaerobic method under thermohas promise. The anaerobic method under thermo-philic conditions offers attractive potentials for hot forest industry effluents, permitting the application of higher organic loading rates and eliminating the need for cooling. Recent experiments have shown that the start-up of thermophilic reactors is not so difficult as previously thought. (See also W91-11467) (Mertz-PTT) W91-11478

ANAEROBIC TOXICITY OF FINES IN CHEMI-THERMOMECHANICAL PULP WASTEWAYERS: A BATCH ASSAY-REACTOR STUDY COMPARISON. Water and Earth Science Associates Ltd., Carp

noxicity of chemi-thermomechanical pulping wastewater was tested in batch assays and in anaerobic sludge blanket reactors. In batch serum bottle tests particulate constituent. particulate constituents were responsible for % of the inhibition of acetoclastic activity, and the soluble (fines-free) fraction accounted for 10-20%. Performance of two 2-stage anaerobic sludge blanket reactor systems was compared, one receiving fines-free and the other unaltered chemireceiving intestree and the other unattered chemi-thermomechanical pulping waste for 140 days. Both reactors became acclimatized to chemi-ther-momechanical pulping and developed a tolerance to resin acid concentrations as high as 300-1500 mg/L in the sludge bed. The fines-free reactor was mg/L in the sludge bed. The fines-free reactor was superior throughout, but the differences in performance did not reflect the batch test results. At the organic loading rate of 17-22 g soluble chemical oxygen demand/gvolatile suspended solids/day the fines-free treated 100% chemi-thermomechanical waste with 42% removal efficiency and the unaltered chemi-thermomechanical wastes with 38% removal efficiency. Fines accumulation in the sludge bed of the unaltered waste reactor caused a 70% increase in bed volume, resulted in deteriora-

tion of sludge settleability, and led to an increased likelihood of biomass loss. (See also W91-11467) (Author's abstract)

ANAEROBIC BIODEGRADABILITY AND METHANOGENIC TOXICITY OF PULPING WASTEWATERS.

Agricultural Univ., Wageningen (Netherlands). Dept. of Water Pollution Control. R. Sierra-Alverez, S. Kortekaas, M. van Eekert, and G. Lettinga.

Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 113-125, 1991. 5 fig, 5 tab, 57 ref.

Descriptors: "Anaerobic digestion, "Biodegrada-tion, "Methanogenesis, "Pulp and paper industry, "Pulp wastes, "Toxicity, "Wastewater treatment, Chemical oxygen demand, Fatty acids, Lignin, Methane, Methane bacteria.

The effect of various pulping conditions and different lignocellulosic feedstocks on the anaerobic treatability of pulping wastewaters was evaluated. Wastewaters were prepared from lignocellulosic feedstocks commonly used in the forest industry, paraely pine, appure and hirch wood and wheat recastocks commonly used in the forest industry, namely, pine, spruce and birch wood, and wheat straw. The pulping conditions used were representative of those applied in thermomechanical and soda pulping processes. The anaerobic biodegradability and the methanogenic toxicity of the various wastewaters were evaluated in standardized batch bioassays using anaerobic granular sludge. The acidification of the thermomechanical pulping wastawaters (convenience of CIV) wastewaters were non-live for the thermomechanical pulping wastewaters (conversion to CH4 and volatile fatty acids) ranged from 68-87% of the total chemical oxygen demand, indicating their high anaerobic biodegradability. Thermomechanical pulping wastewaters were non-live for the conversion of the c wastewaters were non-toxic to methane bacteria at vastewaters were non-tone to methane outcerns at concentrations expected in paper mill wastewaters. No inhibition was observed at 110 g chemical oxygen demand/L. In contrast, wastewaters preoxygen demand/L. In contrast, wastewaters prepared in alkaline conditions were poorly biodegradable (approximately 50% acidification) and they caused severe inhibition of the methanogenic activity. The 50% inhibitory concentrations ranged from 2.1 to 5.4 g chemical oxygen demand/L. Additional experiments showed that wood resin components, poorly solubilized at acidic to neutral pH, but easily extractable in alkali, are responsible for most of the methanogenic toxicity observed in alkaline pulping wastewaters. These results indicated that contact of wood with alkali contributes significantly to increase the methanogenic toxicity significantly to increase the methanogenic toxicity. significantly to increase the methanogenic toxicity of the pulping wastewater. Descriptors: \*Biological treatment, \*Detoxifica-Descriptors: "Diological treatment, "Detoxinic, on "Fungi, "Pulp and paper industry, "Tannins, "Wastewater treatment, "Wood wastes, Aerobic treatment, Aspergillus, Biodegradation, Hydrogen ion concentration, Toxicity.

Debarking effluents of the forest industry are se-verely toxic waste streams due to their high tannin content. The treatment and detoxification of decontent. The treatment and detoxification of de-barking wastewater with tannin tolerant fungi was investigated. Aspergillus niger was cultivated on aqueous bark extracts and the toxicity was assayed utilizing methanogenic bacteria as the test orga-nism. Sterilized aqueous extracts of spruce bark were diluted to 5.2 g COD/L containing 2.7 g tannin COD/L in either citrate or tartrate buffer and incoulsted with A. niger sprose. During for and inoculated with A. niger spores. During four day aerobic fermentations with citrate buffer, the day aerobic termentations with currate outrer, the elimination of unfiltered COD was 28% and for soluble chemical demand, 63%. The apparent yield of biomass averaged 34% of the extract COD 12% of the extract COD was tannins adsorbed on the ngal biomass. The decrease in the tannin concen-

### **Group 5D—Waste Treatment Processes**

tration was 50%. According to gel chromatogra-phy results, the original oligomeric tannins that resisted biodegradation were those of the highest resisted biodegradation were those of the ingness molecular weight. The toxicity was only partially reduced by the fermentation. During the tartrate buffered fermentations, the pH rose due to the metabolism of the organic acid in the buffer. The rise in pH beyond 6 promoted autoxidative reactions that caused extensive polymerization of the tannins which resisted biodegradation. This resulted not only in an enhanced elimination of the tannins but also in a complete detoxification of the tanniss but also in a complete detoxification of the extracts. Similar levels of detoxification could be obtained in sterile un-inoculated extracts by autoxidation alone (raising the pH and aerating the extracts). Extracts fermented in citrate buffer could be completely detoxified by a subsequent autoxidation treatment. The exclusion peak of the gel chromatograms obtained from the highly autoxidized samples accounted for 53% of the ultraviolet absorbance, whereas no exclusion peak was present in the unoxidized extracts. For the biological treatment and detoxification of the debarking wastewaters, it is recommended that the cultivation of tannin tolerant funit followed by short wastewaters, it is recommended that the cuttiva-tion of tannin tolerant fungi followed by short autoxidation treatments that polymerized the oligo-meric tannin fraction resisting biodegradation to nontoxic high molecular weight polymers. EFFECT OF NSSC SPENT LIQUOR ON GRAN-ULE FORMATION AND SPECIFIC MICROBI-AL ACTIVITIES IN UPFLOW ANAEROBIC

REACTORS.
National Research Council of Canada, Montreal (Quebec). Montreal Lab.

S. R. Guiot, L. Lavoir, J. A. Hawari, and R.

Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 139-148, 1991. 3 fig, 4 tab, 20 ref.

Descriptors: \*Anaerobic treatment, \*Lignin, \*Pulp and paper industry, \*Pulp wastes, \*Wastewater treatment, Biodegradation, Biomass, Calcium, Chemical oxygen demand, Sludge bed, Sulfite liquors, Suspended solids.

The capability of sulfonated lignin to induce the flocculation of anaerobic sludge in upflow wastewater treatment was evaluated. Two upflow anaerobic sludge bed-filter reactors fed with a synthetic sugar waste were operated at a specific loading rate of 0.6 to 1.8 g of chemical oxygen loading rate of 0.6 to 1.8 g of chemical oxygen demand per g of volatile suspended solid per day. One of these reactors was stepwise supplemented with a spent liquor rich in sulfonated lignin from a neutral sulfite semi-chemical (NSSC) pulping plant to reach an addition rate of 0.17 g sulfonated lignin/g volatile suspended solids per day; 50% of the sulfonated lignin was adsorbed onto the biomass. This resulted in pre-granulation of the anaer-obic sludge: 50-60% of the biomass was in particles > 0.3 mm versus 70-80% with a sizes < 75 micrometers in the control reactor. In addition, the sulfonated lignin supplementation slightly enhanced the specific metabolic activities of the biomass. Calcium ion addition following the sulfonat-ed lignin treatment enhanced the stability and the density of the aggregates. (See also W91-11467) (Author's abstract) W91-11482

THERMOPHILIC ANAEROBIC TREATMENT OF SULFATE-RICH PULP AND PAPER INTE-GRATE PROCESS WATER,

GRAIL FRUCESS WATER.

Descriptors: \*Anaerobic treatment, \*Pulp and paper industry, \*Pulp wastes, \*Sulfite liquors, \*Wastewater treatment, Chemical oxygen demand, Patty acids, Industrial wastes, Sludge digestion,

Anaerobic treatment of sulfate-rich (chemical oxygen demand/SO4 ratio 1.4-2.1) clarified whitewater from a thermomechanical pulping

process was studied in three laboratory-scale upflow anaerobic sludge blanket reactors at 55 C and in batch digesters at 55 and 65 C. Different and in batch digesters at 55 and 65 C. Different seed materials were used in the upflow anaerobic sludge blanket reactors. The highest chemical oxygen demand removal efficiency (effluent sulfide stripped) achieved was approximately 65% in the upflow anaerobic sludge blanket reactors. About 55% chemical oxygen demand removal efficiency was obtained at a loading rate of about 41 kg chemical oxygen demand/cubic m/day in the upflow anaerobic sludge blanket reactor seeded with themposhilic sludge cultivated with volatile with thermophilic sludge cultivated with volatile fatty acids. The total sulfide present in the liquid natty acids. The total sumoe present in the inquine phase after anaerobic treatment accounted for approximately 65-78% of the removed chemical oxygen demand in the batch digesters and 15-61% in the upflow anaerobic sludge blanket reactors. Sulfate reduction was almost complete in the batch digesters, whereas about 24-64% of sulfate was reduced in the upflow anaerobic sludge blanket resectors. Acetets willivation for culfate reductions are successived to the supplication for culfate reductions. reactors. Acetate utilization for sulfate reduction was apparent in the batch digesters, whereas that could not be demonstrated in the upflow anaerobic sludge blanket reactors. Sulfate reduction in the upflow anaerobic sludge blanket reactors was obviously substrate limited. Thermophilic anaerobic treatment is a viable alternative for the treatment of warm sulfate rich thermomechanical pulping process water. (See also W91-11467) (Author's abstract) W91-11483

BIODEGRADABILITY OF CHLORINATED ORGANIC COMPOUNDS IN PULP BLEACH-ING EFFLUENTS.

New York Univ. Medical Center, NY. Dept. of Microbiology.

Microbiology. M. Haggblom, and M. Salkinoja-Salonen. Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 161-170, 1991. 3 fig, 4 tab, 36 ref.

Descriptors: \*Biological treatment, \*Bleaching wastes, \*Chlorinated hydrocarbons, \*Industrial wastes, \*Pulp wastes, \*Wastewater treatment, Aerobic treatment, Anaerobic digestion, Biological oxygen demand, Chemical oxygen demand, Fluidized beds, Kraft mills, Pulp and paper industry.

The biodegradability of displacement bleaching effluents of kraft pulping was studied. A sequential treatment with an anaerobic fluidized bed and an aerobic trickling filter was effective in degrading the chlorinated high and low-molecular weight the chlorinated high and low-molecular weight material. The treatment significantly reduced the chemical oxygen demand, biological oxygen demand and the organic chlorine of the wastewater. Chemical oxygen demand and biological oxygen genand reduction was greatest in the aerobic process whereas dechlorination was significant in the anaerobic process. Less than 3% of the chemical oxygen demand removed was generated to sludge. With the combined aerobic and anaerobic treatment over 65% reduction of organic chloric treatment over 65% reduction of organic chloric bic treatment over 65% reduction of organic chlorine and over 75% reduction of chlorinated phenoinc and over 1996 reduction of chiornated pheno-lic compounds was observed. The chemical oxygen demand/organic chlorine ratio of the wastewater was similar before and after treatment, indicating that the chlorinated material was as biodegradable as the nonchlorinated. Microbes cabiodegradable as the nonchlorinated. Microbes capable of mineralizing pentachlorophenol constituted approximately 3% of the total heterotrophic microbial population in the aerobic trickling filter. Two aerobic polychlorophenol degrading Rhodococcus strains were able to degrade polychlorinated phenols, guaiacols and syringols in the bleaching effluent. Descriptors: \*Aerobic digestion, \*Dichlorophenols, \*Fluidized bed process, \*Phenols, \*Pulp

wastes, \*Wastewater treatment, Biodegradation, Chemical properties, Chlorinated hydrocarbons, Pulp and paper industry.

Dichlorophenol degradation was studied under oxic conditions using celite carrier material for immobilization of microorganisms in fluidized-bed reactors. Stoichiometric release of chloride and total organic carbon removal from 2,4-dichlorophenol and 2,6-dichlorophenol indicated complete mineralization at hydraulic retention times of 1 hour for 2,4-dichlorophenol and 3 hours for 2,6-dichlorophenol. Gas chromatograph/mass spectro-photometer analyses showed no dichlorophenols or intermediary metabolites in the effluents. No 3,5-dichlorophenol degradation could be observed in the fluidized bed reactor. Microorganisms were in the fluidized bed reactor. Microorganisms were isolated from the reactor and their ability to degrade 2,4-dichlorophenol was evaluated in bioassays. 2,4-dichlorophenol degradation was slow by gram-variable rod and by gram-positive micrococcus, whereas the mixture of these isolates readily degraded 2,4-dichlorophenol. The results show that the amendability of dichlorophenol to aerobic biodegradation depends on the location of chlorine substituents in the ring structure. Dichlorophenol substituents in the ring structure. Dichlorophenol with both chlorine substituents in the meta position was recalcitrant towards aerobic degradation, whereas dichlorophenols with chlorine substituents whereas dictinophenois with chlorine substituents in ortho-para or ortho-ortho positions were readily degradable. It appears that oxic fluidized bed technology is a potential method for high-rate removal of chlorophenol contaminants from water. (See also W91-11467) (Mertz-PTT) W91-11485

TREATMENT OF BLEACHING EFFLUENTS IN AEROBIC/ANAEROBIC FLUIDIZED BIOFILM SYSTEMS.

Biodegradation of chloroorganic compounds in real industrial bleaching effluents (chlorination and extraction), with adapted biofilm in fluidized sand bed reactors, was studied under aerobic and anaer-obic conditions. The effluents were only diluted and supplied with mineral nutrients. Two reactor combinations were compared with a single stage aerobic digestor. In the anaerobic-aerobic reactors in series, the effluents were first treated anaerobically followed by an aerobic reactor in a single pass. In the anaerobic-aerobic recycle reactor, the reactor content was periodically moving back from aerobic to anaerobic fluidized beds. The reacfrom aerobic to anaerobic fluidized beds. The reac-tors were running continuously for one year. The most significant differences observed were be-tween aerobic and anaerobic single reactors. Gen-erally anaerobiosis reduced performance in terms of global parameters (chemical oxygen demand, nonpurgeable organic carbon, adsorbable organic halogen). With a residence time of 18 hours for each reactor, chemical oxygen demand and adsorb-able organic halogen typically decreased by 15-32% for each aerobic reactor system, where 32% for each aerobic reactor system, whereas a decrease of typically 4-15% was observed in the purely anaerobic system. From gas chromatograph and gas chromatograph/mass spectrometer analysis it was evident that in the anaerobic reactors, 2,4,6-trichlorophenol was first converted to 2,4-dichlorophenol. In all three systems 2,4,6-trichlorophenol. ophenol and dichlorophenols were almost com-pletely removed. (See also W91-11467) (Author's abstract) W91-11486

ONSET OF LIGNIN-MODIFYING ENZYMES, DECREASE OF AOX AND COLOR REMOVAL

### Waste Treatment Processes—Group 5D

BY WHITE-ROT FUNGI GROWN ON BLEACH PLANT EFFLUENTS, Helsinki Univ. (Finland). Dept. of General Micro-

biology. V. P. Lankinen, M. M. Inkeroinen, J. Pellinen, and

A. I. Hatakka. Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 189-198, 1991. 5 fig, 39 ref.

Descriptors: \*Biological treatment, \*Bleaching wastes, \*Fungi, \*Pulp wastes, \*Wastewater treatment, Biodegradation, Chlorinated hydrocarbons, Color, Enzymes, Pulp and paper industry.

Decrease of adsorbable organic chlorine is becoming the most important criterion for the efficiency of pulp mill effluent treatment in the 1990s. Two methods, designated MYCOR and MYCOPOR, that utilize the white-rot fungus Phanerochaete chrysosporium have been developed for the color removal of pulp mill effluents, but the processes also have a capacity to decrease the amount of chlorinated organic compounds. Lignin peroxi-dases (ligninases) produced by P. chrysosporium may dechlorinate chlorinated phenols. The use of selected white-rot fungi in the treatment of El-stage bleach plant effluent was studied. Phlebia radiata, Phanerochaete chrysosporium and Merulius (Phlebia) tremellosus were compared in shake flasks for their ability to produce laccase, lignin peroxidases and manganese-dependent peroxidases and to remove color from a medium containing effluent. Softwood bleaching effluents were treated by carrier-immobilized P. radiata in 2-liter bioreacby carrier-immobilized P. radiata in 2-liter bioreac-tors and a IO-liter Biostat-fermentor. Dechlorina-tion was followed using Cl(-) ion and organic chlorine determinations. All fungi removed the color of the effluent. In P. radiata cultivations organic chlorine decrease was about 4 mg/L in organic chlorine decrease was about 4 mg/L in one day. Apparent lignin peroxidase activities as determined by veratryl alcohol oxidation method were negligible or zero in a medium with organic chlorine content of about 60 mg/L, prepared using about 20% of softwood effluent. However, the purification of extracellular enzymes implied that large amounts of lignin peroxidases were present in the medium and, after the purification, in active form. Enzyme proteins were separated using anion exchange chromatography, and they were further characterized by electrophoresis to reveal the kind of enzymes that were present during organic chlo-rine decrease and color removal. The most charac-teristic lignin peroxidase isoenzymes in effluent media were ligninases. (See also W91-11467) (Au-

DECREASE OF POLLUTANT LEVEL OF BLEACHING EFFLUENTS AND WINNING VALUABLE PRODUCTS BY SUCCESSIVE FLOCCULATION AND MICROBIAL FLOCCULATION GROWTH.

Descriptors: \*Biological treatment, \*Bleaching wastes, \*Flocculation, \*Fungi, \*Pulp wastes, \*Waste recovery, \*Wastewater treatment, \*Water pollution control, Biodegradation, Chlorinated hydrocarbons, Glucose, Microorganisms, Pulp and paper industry, Sulfates.

The bulk of organic matter from spent bleaching effluent, either from chlorination and extraction stages or a mixture of both, can be precipitated with polycationic polymers. The mixtures of po-lyethylenimine and modified (containing cationic side groups) starches, can precipitate from bleach-ing effluent about 75% of adsorbable organic chloing effluent about 75% of adsorbable organic Chlorine, 59% of chemical oxygen demand and 80% of color. These mixtures contained less polyimine in comparison to when polyimine was used alone, thus saving material costs. After removal of chloroorganics of high molecular mass by precipitation growth of microorganisms in spent bleaching effluent was facilitated. The supernatant of the treated

spent bleaching effluent supplemented with glucose and ammonium sulfate supported active growth of fungi from different genera, particularly from Aspergillus spp., Pennicillium spp., Basidiomycetes, and Aureobasidiu. The fungi tested showed appreciable degradation activity regarding monochlorophenols, as well as additional reduction of adsorbable organic chlorine. During the growth in the treated spend bleaching effluent, Aurebasidium pullulans decreased the content of adsorbable organic chlorine remaining after precipitation, and at the same time synthesized and excreted in a surrounding media exopolysaccharides. Pollulan, synthesized in appreciable level by Aureobasidium sp., could easily be isolated from the media. Isolated exopolysaccharides synthesized in spent bleaching effluent might be considered as an additional benefit that eventually will be able to reduce further the running costs of the spent bleaching effluent treatment. (See also W91\_114671 (Author's abstract) will be able to reduce the training costs of the spent bleaching effluent treatment. (See also W91-11467) (Author's abstract) W91-11488

TREATMENT OF BLEACH-PLANT EF-FLUENTS WITH MEMBRANE FILTRATION AND SORPTION TECHNIQUES.

O. Ekengren, J. E. Burhem, and S. Filipsson. Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 207-218, 1991. 6 fig, 7 tab, 19 ref, 3

Descriptors: \*Bleaching wastes, \*Filtration, \*Membrane filters, \*Pulp wastes, \*Sorption, \*Wastewater treatment, Chemical oxygen demand, Chlorinated hydrocarbons, Pulp and paper industry, Reverse osmosis, Toxicity, Ultrafiltration, Waste disposal.

Laboratory experiments have been run with the combination of ultrafiltration and sorption techniques/reverse osmosis. The use of negatively charged membranes improved both the filtration capacity (flux) and the rejection of organochlorine compounds. The combination of ultrafiltration and reverse osmosis used to treat retention in the causcompounds. In e combination of ultrafilitation and reverse osmosis used to treat retention in the caustic extraction stage showed high removal of chemical oxygen demand, adsorbable organic chlorine and chloride ions (98.8-99.9%). The content of adsorbable organic chlorine in the reverse osmosis permeate was 0.08 g per ton pulp. The ultrafilitation of three different total bleachery effluents showed a chemical oxygen demand removal of 55-60% and an adsorbable organic chlorine removal of 65-75%. The decrease in toxicity was about 50% and the removal of substances with a bioaccumulation potential was around 90%. The treatment of this ultrafilitation-permeate with a weak-base anion exchanger gave even higher removal efficiencies, especially for the chlorophenolic compounds (93%), and the toxicity decreases five times. The sorbent did not show any remarkable loss in removal efficiency during the 48 loading and reactivation cycles. When treating the total bleachery effluents the combination of ultrafiltration and reverse osmosis also showed high removal efficiencies. It is not meaningful to make a cost tion and reverse osmosis also showed high removal uon and reverse osmosis also showed high removal efficiencies. It is not meaningful to make a cost estimation before these combinations have been studied for longer periods, on larger scales and with wide range of effluents. The problem of the final destruction of the pollutants that have been removed remains to be solved. (See also W91-11467) (Author's abstract)

MEMBRANE FILTRATION COMBINED WITH BIOLOGICAL TREATMENT FOR PURIFICA-TION OF BLEACH PLANT EFFLUENTS. Swedish Environmental Research Inst., Stock

B. Boman, M. Ek, W. Heyman, and B. Frostell. Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 219-228, 1991. 3 fig, 6 tab, 14 ref.

Descriptors: \*Aerobic treatment, \*Biological treatment, \*Bleaching wastes, \*Filtration, \*Kraft mills, \*Membrane filters, \*Pulp wastes, \*Wastewater treatment, Aerated lagoons, Biological oxygen demand, Chemical oxygen demand, Industrial wastes, Pulp and paper industry.

A bleach plant effluent from softwood kraft pulping was treated in the laboratory with a combination of ultrafiltration and different biological methods. The E-stage effluent was first membrane filtered using membranes with a nominal cut-off of 8000 Dalton. In the filtration, a concentration factor of 15 was used at 55 C. The treatment resulted in 89% adsorbable organic chlorine removal and 87% chemical oxygen demand removal. Calculated in relation to the actual flows of E-stage and (C+D)-stage effluent at the mill, this corresponded to adsorbable organic chlorine removal of 20% and chemical oxygen demand of 41%. Before the biological treatment, the permeate 41%. Before the biological treatment, the permeate was mixed with (C+D)-stage effluent and treated in three parallel biological systems, an aerated lagoon with and without solids recycle, an airlift system with a mixed fungal Hora and an anaeroom filter. For the lagoon treatment, a hydraulic retenstem with a mixed fungal flora and an anaerobic tion time of 7 days was used at biomass concentra-tions of 70, 350 and 480 mg total suspended solids/ tions of 70, 350 and 480 mg total suspended solids/ L and 20-22 C. The fungal system was evaluated at retention times of 5.5, 11 and 22 hours, 770 mg total suspended solids/L and 37 C. For the anaero-bic filter, retention times of 1, 5, and 25 hours at a temperature of 35 C were used. Very promising results were obtained with the combination of physical and biological treatment. The aerated lagoon with solids recycle gave the best results with 66% of adsorbable organic childring 73% of with 66% of adsorbable organic chlorine, 72% of chemical oxygen demand and 95% of the biologi-cal oxygen demand being removed in the com-bined process. The anaerobic filter also gave good results, but in practice a small aerobic post-treat-ment would probably be necessary. The three sys-tems were also evaluated for the removal of chlortems were also evaluated for the removal of the inated phenolic compounds and acute toxicity according to the Microtox test. The results suggest combination of membrane filtration a aerobic/aerobic or just aerobic treatment would be an attractive way to handle kraft mill bleach plant effluents. TREATMENT OF PULP-BLEACHING EF-FLUENTS BY ACTIVATED SLUDGE, PRECIPI-TATION, OZONATION AND IRRADIATION. Universitaet fuer Bodenkultur, Vienna (Austria).

Inst. fuer Wasservorsorge.
R. Haberl, W. Urban, P. Gehringer, and W. Szinovatz.

Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 229-239, 1991. 3 fig, 5 tab, 18 ref.

Descriptors: \*Activated sludge process, \*Bleaching wastes, \*Chemical precipitation, \*Irradiation, \*Ozonation, \*Pulp wastes, \*Wastewater treatment, Biodegradation, Biological oxygen demand, Chemical oxygen demand, Color, Flocculation, Kraft mills, Sulfite liquors.

The non-biodegradability of conventional pulp bleaching effluents represent a major wastewater disposal problem. Experience has shown that an extra stage treatment process is necessary to purify pulp bleaching sewages. The first stage (precipita-tion/flocculation oxidation with ozone, or highenergy radiation) allows resistant organic substances to be changed to biodegradable substances. The main elimination should be done in a biological stage, and remaining concentrations can be eliminated by a final treatment. Effluents of sulfite and kraft processes were treated to achieve the following elimination rates: about 90% five-day biological oxygen demand, 30-40% chemical oxygen demand, and 20-30% adsorbable organic chlorine. Precipitation with lime in addition to flocculation resulted in reduction rates of 40% chemical oxygen demand, 50% adsorbable organic chlorine, and 70% of the color. Such a pretreatment and a subsequent biological treatment in-creased the reduction rates to >95% five-day bio-logical oxygen demand, 70-80% chemical oxygen demand and 70-85% color. Treatment with ozone, demand and 70-57% COIOT. I reatment with a Coine, with and without simultaneous gamma-irradiation was carried out with native bleaching effluents at different temperatures and at different pH. These preliminary tests turned out to be unsatisfactory, probably because of the high amount of easily biodegradable substances in this sewage, which

### **Group 5D—Waste Treatment Processes**

reduced the effectivity of ozone/radiation. (See also W91-11467) (Mertz-PTT)

INVESTIGATION OF ANAEROBIC REMOVAL AND DEGRADATION OF ORGANIC CHLO-RINE FROM KRAFT BLEACHING WASTEWATERS.

Washington Univ., Seattle. Dept. of Civil Engi-

J. F. Ferguson, and E. Dalentoft. Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 241-250, 1991. 5 fig, 9 ref.

Descriptors: \*Anaerobic digestion, \*Bleaching wastes, \*Chlorinated hydrocarbons, \*Dechlorination, \*Kraft mills, \*Wastewater treatment, Acetates, Biological treatment, Hydrogen, Methane, Pulp and paper industry, Pulp wastes.

A study of anaerobic removal of adsorbable organ-A study of anaerooic removal of ausoroanic organ-ic halide from kraft bleaching wastes has been conducted, using bottle bioassay techniques. The anaerobic cultures were fed either acetate or hy-drogen and were able to remove from 40-65% of drogen and were able to remove from 40-65% of the adsorbable organic halide. The removal mecha-nism and the role of an adapted anaerobic consorti-um was investigated. Results indicated some bio-logical removal, but significant amounts of sorp-tion or degradation did not seem to require microbial activity. Significant inhibition of methanogenic activity was found in some tests. The evidence suggests that abiotic processes may be responsible for a major fraction of the removal observed. Wastewater presence is quite inhibitory to methan-ogenesis, more to acetoclasts than to hydrogen utilizers. When wastewater is present, substantial diversion of the electron donor, either acetate or hydrogen, from methane production has been seen.
Although the electron donor diversion far exceeds that necessary to reduce the organic chlorine, it is certainly possible that microbes carrying out re-ductive dehalogenation are involved in the use of ductive dehalogenation are involved in the use of hydrogen or acetate. In some tests the adsorbable organic halide removal clearly was not synchronous with methane production, indicating possible involvement of a microbial population other than methanogenous. Both these findings suggest that a growth supporting, oxidation/reduction reaction may be occurring in the presence of wastewater. (See also W91-11467) (Mertz-PTT)

### CRITERIA FOR NUTRIENT-BALANCED OP-ERATION OF ACTIVATED SLUDGE PROC-ESS.

Vysoka Skola Chemicko-Technologicka, Prague (Czechoslovakia). P. Grau.

Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 251-258, 1991. 2 tab, 14 ref.

Descriptors: \*Activated sludge process, \*Limiting nutrients, \*Nitrogen, \*Phosphorus, \*Pulp wastes, \*Wastewater treatment, Ammonia, Iron, Magnesium, Molybdenum, Nitrates, Nutrient requirements

Though N and/or P are most frequently the limiting nutrients in industrial applications of the activated sludge process, there are other potentially limiting nutrients, especially Fe, Mg and Mo. Two different mechanisms exist in nutrient-limited biomass: multiple limitation of the growth rate and single nutrient limitation of the biomass crop. It is suggested that effluent concentrations of both NH3-N and NO3(-)-N be used as control parameters for nitrogen dosing adjustment. Dosing of both ammonia and nitrate to supplement nitrogen is considered for situations sensitive to total nitrogen discharge. Excess of nutrients in the effluent contributes to eutrophication and has to be minicontributes to eutrophication and has to be mini-mized. Lack or deficiency of nutrients results in lowered treatment efficiency and in sludge bulking. Addition of nutrients must therefore controlled in such a way that none of the extremes takes place. The rational for this is that excessive concentration of nitrate can be easily denitrified while excessive concentration of ammonia is not easy to remove in pulp and paper wastewater treatment plant conditions. Minimum soluble phosphorus concentrations of about 0.5 mg/L have been reported as required

for reliable operation. In many cases, however, lower concentrations are maintained without any adverse effects to the process. Soluble orthophosphate is not an adequate control parameter for phosphate dosing since some of the phosphate precipitates can be utilized by microorganisms. Ap-propriate methods for assessing their availability to microorganisms in real situations are still missing. (See also W91-11467) (Mertz-PTT)

### NITROGEN AND PHOSPHORUS LIMITS FOR NUTRIENT DEFICIENT WASTEWATERS.

CM Consult, Ringhoffer Strasse 72, D-8044 Unterschleissheim, Germany.

C. H. Mobius.
Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 259-267, 1991. 5 fig, 2 tab, 7 ref.

Descriptors: \*Activated sludge process, \*Biological treatment, \*Nitrogen, \*Phosphorus, \*Pulp wastes, \*Wastewater treatment, \*Water pollution control, Biological oxygen demand, Denitrifica-tion, Industrial wastes, Nitrification, Nutrient requirements, Pulp and paper industry

Biological treatment of nutrient deficient industrial Biological treatment of nutrient deficient industrial wastewaters, such as those of the pulp and paper industry, require the addition of nitrogen and phosphorus. As a certain surplus is necessary, both elements will be found in the effluent in varying the control of the contr concentrations. Activated sludge treatment uses 5 parts of N and one part of P for elimination of 100 parts biological oxygen demand. In-plant optimiza-tion generally leads to about 3.5 parts of N and 0.6 parts of P for 100 parts of biological oxygen demand. N is normally added as urea and P as phosphoric acid. Optimized nutrient dosages usually results in concentrations of 1 mg/L of both ammonia N and phosphate P in the treated effluent, with maximum concentration in 24-hour mixed samples of more than 10 mg/L for both N and P Water quality requirements will impose general limitations on N and P concentrations in treated effluents. Nutrient dosage should become state of the art in the near future. The next step will be a loading dependent dosage. No results of technical operation are known which show the effluent concentrations obtainable with this techniques. For centrations obtainable with this techniques. For cases in which limits cannot be met with this strategy the possibilities of nitrification, denitrification and biological P removal were examined for nutrient deficient wastewaters. Results showed that nitrification will work at low ammonia concentrations, however, no steady nitrification would be obtained. Denitrification, on the other hand, seems to be difficult with low nitrate concentrations. At present, no technical process meeting stringent total N or total inorganic N limits is known to exist for nutrient deficient wastewaters. Low P concentrations in the effluent can only be achieved by tertiary treatment, preferably final flocculation filtration processes. (See also W91-11467) (Mertz-PTT) W91-11494

## CONDUCTIVITY FOR NUTRIENT CONTROL IN CTMP WASTEWATER TREATMENT. Scanyironment, St Ror, S-386 00 Farjestaden,

B. Rosen, R. Modell, L. Bruneau, and L

Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 269-275, 1991. 3 fig, 3 tab, 5 ref.

Descriptors: \*Activated sludge process, \*Chemical treatment, \*Conductivity, \*Process control, \*Pulp wastes, \*Wastewater treatment, Analytical methods, Biological oxygen demand, Chemical oxygen demand, Organic matter, Pulp and paper industry.

At the 60,000 ton/year CTMP (chemo-thermo-mechanical pulping) mill at Vaggerty in southern Sweden, which began operations in May 1989, a two-stage activated sludge plant with pre-precipi-tation and post-precipitation, has been installed for reducing the incoming biological oxygen demand from 12 tons per day to less than 500 kilo per day. The results normally show a biological oxygen demand reduction of 96-98% and a chemical

oxygen demand reduction of 75-85%, or less than 250 and 1800 kg/day in the effluent. The possible use of conductivity as the measurement of the incoming organic content was studied. Observations indicated a correlation between chemical oxygen demand in the influent and conductivity. The amount of chemicals being used in the CTMP process influence the dissolving of organic matter into the wastewater. Conductivity meters are very robust and reliable, and the possibility of using such a simple method for measurement of the such a simple method for measurement of the organic content in the wastewater lead to installaorganic content in the wastewater lead to installa-tion of instruments. For actual wastewater, the correlation between conductivity and the chemical oxygen demand-content in the influent was good. As the chemical oxygen demand in the influent can be predicted with less than 20% deviation by the use of conductivity measurement, the dosage of nutrient can be easily and reliably controlled. ## PRACTICAL EXPERIENCE WITH BIOLOGICAL REMOVAL OF PHOSPHORUS FROM PULP AND PAPER MILL EFFLUENTS,

Metsa-Seria Oy, 08800 Kirkniemi, Finland.

Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 277-286, 1991. 2 fig, 1 tab, 23 ref.

Descriptors: \*Biological treatment, \*Phosphorus, \*Phosphorus removal, \*Pulp and paper industry, \*Pulp wastes, \*Wastewater treatment, Aerobic treatment, Anaerobic digestion, Bacteria, Finland, Water pollution control, White water.

Effluent discharges in Finland have decreased steadily during the past two decades. The two traditionally largest polluters, the pulp and paper industry and the municipalities, have been able to reduce their discharges by 70-90% since 1970. Presently, Finland's total phosphorus discharge is estimated at 3000-6000 ton/year. The forest industry discharges about 800 tons/year. Removal of participals from wastewaters by hiological means. try discharges about 800 tons/year. Removal of nutrients from wastewaters by biological means, without the utilization of chemicals, has been among the principal goals of wastewater research for many years. Worldwide, a few hundred treatment plants utilize biological P removal. Nearly all the plants constructed so far are treating municipal sewage. There are numerous processes and process modifications able to remove more than 90% of the phosphorus from the effluents. All the processes are modifications of the conventional activated es are modifications of the conventional activated sludge method. A common feature is that the wastewater and/or biological sludge is subjected to anaerobic conditions at some stage of treatment, preferably before being led off for aeration. This creates favorable conditions for the growth of bacteria able to absorb excessive amounts of P. Of the several different bacteria able to bind P, the so-called polyP bacteria, the best known is Acinetobacter spp. At plants where biological P removal is practiced, Acinetobacter can represent up to 2/3 of the bacterial population. Pulp and paper effluents are ideally suited for biological P removal; waters are warm, suitable food is available in quantity and the concentration of P is low. Metsa-Serla Oy and the concentration of P is low. Metsa-Serla Oy and tis subsidiary have pulp and paper production at eight locations in Finland. Total P discharge is about 300 kg/day. At the beginning of 1989, plant-scale experiments were started at the Kirkniemi paper mill. The results have been promising, with the highest removal rates obtained at over 90%. The good P removal at the plant is biological in nature and a polyP mechanism is probably involved. The occurrence of Acinetobacter in large quantities in the white water system of the Kirkniemi plant could explain the rapid start-up of the P removal process. Descriptors: \*Biological treatment, \*Chlorinated hydrocarbons, \*Dehalogenation, \*Pulp wastes, \*Wastewater treatment, Aerated lagoons, Aerobic treatment, Chlorine, Industrial wastes, Kraft mills, Pulp and paper industry, Wastewater re

A single-stage aerobic biological treatment system was developed specifically to convert organically bound chlorine to inorganic chloride. The pilot reactor for wood preservative wastewater was an aerobic, packed-bed, upflow reactor. The pilot reactor for kraft wastewater was of a considerably different configuration. Within an operating kraft aerated lagoon, five reaction zones were created in series. Each zone consisted of an open aeration area followed by a packed media area. In initial series. Each zone consisted of an open aeration area followed by a packed media area. In initial laboratory tests, greater than 90% reduction of adsorbable organic halide was achieved in synthetic dichlorophenol, commercial pentachlorophenol, and combined kraft wastewaters, and less than a week was required for startup/acclimation. A sixmonth field test of the process on a pentachlorophenol, wastewater, was very successful under the process of the proc phenol wastewater was very successful under highly variable influent conditions. No chlorinated byproducts were detected, and measurements strongly indicated that dehalogenation had occurred. Recent experiments found C1/E1 wastewater to be most easily treatable by the aerowastewater to be most easily treatable by the aero-bic process, followed by combined lagoon influent, E1 wastewater, and finally lagoon effluent. How-ever, results have indicated that application of the treatment process to kraft adsorbable organic halide reduction can become feasible only if fur-ther process improvements can be made. FACTORS AFFECTING THE REMOVAL AND DISCHARGE OF ORGANIC CHLORINE COM-POUNDS AT ACTIVATED SLUGGE TREAT-MENT PLANTS. Finnish Pulp and Paper Research Inst., Helsinki. R. Saunamaki, K. Jokinen, R. Jarvinen, and M.

Savolainen.
Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 295-307, 1991. 11 fig, 4 tab, 30 ref.

Descriptors: \*Activated sludge process, \*Chlorinated hydrocarbons, \*Halides, \*Phenols, \*Pulp wastes, \*Wastewater treatment, Aerobic treatment, Anaerobic lagoons, Biological wastewater treat-ment, Industrial wastes, Pulp and paper industry, Wastewater disposal.

Tests were performed to find out to what extent Tests were performed to find out to what extent and in what way organic chlorine compounds (adsorbable organic halides, chlorinated phenols) are reduced in an activated sludge process. In an extended aeration activated sludge plant the reduction of adsorbable organic halide was 40-50% and that of chlorinated phenols 70-80%. In a high-load activated what salar the accuracy files removable activated which a lant the accuracy files removable. activated sludge plant the corresponding removals were only 20-30% and 35-55%. The removal oxygen-consuming substances was also lower in the high-load plant. It is evident that most of the chlorinated organics, especially low molar mass compounds, are removed by microbiological action. About 0.05-0.2 kg adsorbable organic halogen/ton of pulp was removed from the system with the excess biosludge, to be mixed with primary sludge and finally either burned or used as landfill. At the extended aeration activated sludge landfill. At the extended aeration activated sludge plant the adsorbable organic halide discharge to the recipient was only 1.3 kg/ton when birch was the chief raw material. The corresponding figure at the high-load plant was 65% if the fiber raw material was softwood. A detailed study revealed differences in the microorganisms present in the aeration sections of the plants. For example, there were practically no protozoa present in the high-load plant, and the number of species of bacteria was also smaller than in the low-load plant, where thermophilic bacteria and fungi were typically present. Tests carried out under controlled laboratory conditions showed that changes in conditions in the aeration section had little effect on the in the aeration section had little effect on the removal of adsorbable organic halide, but a considerable effect on the removal of low molar mass compounds such as chlorinated phenols. An anaerobic/facultative lagoon before or after the activated sludge process did not improve the removals. Removing colloidal material from biologically

treated effluents had a great influence on adsorbable organic halogens. (See also W91-11467) (Author's abstract)

TREATABILITY OF BLEACHED KRAFT PULP AND PAPER MILL WASTEWATERS IN A NEW ZEALAND AERATED LAGOON TREAT-Waikato Univ., Hamilton (New Zealand). Dept. of

Chemistry.

T. R. Stuthridge, D. N. Campin, A. G. Langdon,
K. L. Mackie, and P. N. McFarlane.

Water Science and Technology WSTED4, Vol.
24, No. 3/4, p 309-317, 1991. 5 fig, 3 tab, 30 ref.

Descriptors: \*Aerated lagoons, \*Biological treatment, \*Bleaching wastes, \*New Zealand, \*Pulp wastes, \*Wastewater treatment, Chlorinated aromatic compounds, Chlorinated hydrocarbons, Kraft mills, Organic matter, Pulp and paper indus-

The effectiveness of the two biological treatment systems operating at a New Zealand bleached kraft softwood integrated pulp and paper mill was assessed. The two systems operated in different configurations. Treatment system A, which received general mill wastewaters and chlorination stage bleaching discharges utilized deep, aerated lagoons and had a 4.5 day retention time. Treatment system B, which received alkali extraction bleaching and nao a 4.5 day retention time. I reatment system B, which received alkali extraction bleaching wastewaters and foul condensates, used a lagoon system with a retention time of 45 days. Detailed chemical analyses of the untreated and treated chemical analyses of the intreated and treated wastewaters were made. Mass balances were calculated for a range of physical parameters and for specific chlorinated and non-chlorinated organic constituents. Significant differences in the treatability of various constituents were found. In particu-lar, while system A was able to reduce levels of lar, white system A was able to reduce levels of adsorbable organic halide by 65%, no significant reduction in adsorbable organic halide occurred in system B. In contrast, system B reduced levels of chloracetic acids by 34%, whereas system A did not achieve any statistically significant removal of these compounds. The treatability of chlorophenolic compounds also differed. System A was unable remove chlorophenols and chloroguaiacols, ile system B did not reduce levels of chlorocatewhile system but not reduce levers of conforcate-cols. These results confirm that the treatability of bleached kraft pulp and paper mill wastewater constituents is dependent upon the characteristics of the treatment systems and the compositions of the wastewaters. TREATMENT TECHNOLOGIES FOR ORGAN-OCHLORINE-CONTAINING SLUDGES AND CONCENTRATES FROM EXTERNAL TREAT-MENT OF WASTEWATERS. PULP AND

Swedish Environmental Research Inst., Stock-

M. Almemark, G. Finnveden, and B. Frostell. Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 319-329, 1991. 7 tab, 36 ref.

Descriptors: \*Chlorinated hydrocarbons, \*Pulp wastes, \*Sludge disposal, \*Sludge treatment, \*Wastewater disposal, \*Wastewater treatment, Activated sludge process, Chemical coagulation, Chlorinated aromatic compounds, Filtration, Pulp and paper industry, Sweden.

Literature data and results from current Swedish research have been used to compile characteristics research have been used to compile characteristics of and disposal method for sludges and concentrates from external treatment of wastewaters from the pulp and paper industry. Very little sludge from aerobic lagoon treatment in Sweden is handled, and most of the solids are deposited in the receiving waters. In North America, Finland and Japan, where activated sludge treatment is used to a great extent, sludge handling is an important part of the kraft mill effluent treatment. Typically, 5-15 kg of dry solids has to be handled per ton of pulp with a process discharge of 15-20 kg of five-day biological oxygen demand. For chemical coagula-tion, the amounts of sludges produced are higher,

typically 40-80 kg dry solids. Especially in Japan, chemical coagulation is used to a great extent. Laboratory and pilot-plant experiments with ultrafiltration of alkaline stage and total bleach plant effluents suggest that concentrates with a total solids content of approximately 20 and 50 kg dry solids are produced. The concentrations of organochlorine compounds in sludges and concentrates have not hitherto been well documented, and nor have not hitherto been well documented, and nor have environmental effects of different disposal methods. Chlorinated phenols, catechols and guaiacols have been found in variable concentrations; chlorinated dibenzodioxins and furans have also been detected. Vacuum filters and especially belt filter presses have been used to dewater sludges. Typical dry solids concentrations achieved vary from 20-35% for primary sludges to 15-20% for secondary sludges, Anaerobic digestion may be applied before dewatering of sludges, and methane yields of 200-400 L CH4/kg volatile solids removed have been reported. Sludge has solids removed have been reported. Sludge has been disposed of in landfills or incinerated. Leachates from landfilliling of pulp and paper industry sludges may contain high levels of soluble organic material, but available information suggests that organochlorine compounds do not leach to a substantial extent. Incineration of pulp mill sludges and concentrates seems to be an increasingly at-tractive method. (See also W91-11467) (Author's abstract) W91-11500

ANAEROBIC TREATMENT OF BLEACHED TMP AND CTMP EFFLUENT IN THE BIOPAQ UASB SYSTEM.

Paques B.V., Balk (Netherlands).

L. H. A. Habets, and A. L. de Vegt. Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 331-345, 1991. 9 fig, 7 tab, 20 ref.

Descriptors: \*Anaerobic digestion, \*Bleaching wastes, \*Chemical treatment, \*Pulp wastes, \*Wastewater reactors, \*Wastewater treatment, Canada, Finland, Hydrogen peroxide, Industrial wastes, Methanogenesis, Pulp and paper industry, Studen.

The effluents from CTMP chemo/thermo/me-chanical pulping) mills are on the one hand too dilute for evaporation and recovery, and on the other hand too highly polluted for conventional aerobic secondary treatment. In the summer of 1986, an extensive research program was started in cooperation with Finnish and Canadian engineercooperation with Finnish and Canadian engineer-ing firms in order to investigate the anaerobic treatability of CTMP effluent, using upflow anaer-obic sludge bed technology. Laboratory studies, as well as on-site pilot work was conducted in Fin-land and Canada. As a results of this research, two land and Canada. As a results of this research, two full-scale plants are in operation. The first plant was started up in October 1988 at Quesnel River Pulp in B.C. Canada, and is treating up to 140 tons of chemical oxygen demand per day in two reac-tors of 3500 cubic m each. The second plant was ready for start-up in January 1990 at the Enso-Gutziet Kotka mill in Finland. The cautious approach for these types of effluents was necessary due to earlier reports on the toxicity of softwood extractives, bleaching agent hydrogen peroxide, complexing agent and high sulfur levels. Besides this, it was necessary to confirm that granular seed sludge would not deteriorate but would develop normally. The behavior of hydrogen peroxide was especially interesting and the high redox potential especially interesting and the high redox potential caused could be resolved in a very cost-efficient way without utilizing chemicals, enzymes or activated sludge. Resin acids were identified to be responsible for reducing methanogenic activity considerably. They were eliminated during aerobic post-treatment to very low levels. Lab studies clearly demonstrated how methanogenic activity could be increased by adding dilution water or aerobically treated effluent. The concentration of the resin acids appeared to be associated with raw aeronically treated efficient. The concentration of the resin acids appeared to be associated with raw material (spruce, fir or pine), the season (summer or winter) and with fine fibrous material in the effluent. Sulfur levels in the effluent were relatively high, but resulting sulfide levels were not toxic to methanogens and chemical oxygen demand/ sulfur ratios were high enough to achieve accepta-

which sulfide was converted to elemental sulfur using colorless sulfur bacteria, Thiobacillus spp. A 4 cubic m biorotor reactor was tested using spp. A A new system for sulfide removal was examined in c m biorotor reactor was tested using sulfide-4 cubic in biorotor reactor was tested using suffice-containing anaerobically treated papermill wastewater. The removal plants were located at a wastewater treatment facility in the Netherlands. The plant treats the wastewater from three separate papermills with a total production approaching 300,000 tons/year. Experiments with lab-scale reactors were conducted in order to assess the feasibility of different kinds of carrier material. Experiments with the pilot-plant biorotor reactor were conducted in order to optimize the sulfide removal process. Important parameters of the process were the flow rate of the wastewater, the flow rate of the required air, the rotation speed of the cage, and kind of carrier material and the H2S concentration in the effluent air. Sulfide removal efficiencies well above 90% were achieved at a hydraulic retention time of 19 minutes, using Pall hydraulic retention time of 19 minutes, using Pall rings of 2.5 cm or Bio-Net 200 as carrier materials. Reticulated polyurethane was not suitable as carrier material for the sulfide removal process in the presence of fatty acids. The results showed that there is a real potential for sulfur recovery from anaerobically treated effluent. (See also W91-11467) (Mertz-PTT) W91-11502

THERMOCATALYTIC AND CHEMICAL TREATMENT OF LIGNIN-ALUMINIUM SLUDGE AND UTILIZATION OF THE RESULTING ADSORBENT-COAGULANT. Leningrad Technological Inst. for the Pulp and Paper Industry (USSR). I. V. Wolf, Y. M. Chernoberezhsky, E. I. Jepifantseva, and A. D. Simonov. Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 357-360, 1991. 2 fig, 1 tab, 2 ref.

Lignin compounds from kraft pulping are slowly biodegradable and usually not removed in the con-ventional biological treatment. Chemical coagulation can be used to improve lignin removal. The Baikal Pulp and Paper Mill in the USSR has a Balkal Pulp and Paper Mill in the OSS has a set tertiary wastewater treatment with aluminum sulfate. The produced lignin sludge contains 18-23% of mineral substances and 77-82% of organic matter. The use of chemicals adds sludge disposal problems and treatment costs. A new sludge disposal problems are treatment costs. A new sludge disposal problems are treatment to the cost of the ligning additional solutions and treatment costs. posal process was developed. The lignin-aluminum sludge from the settling basin was first converted into adsorbent by using a thermocatalytic reactor. The produced adsorbent was further refined to adsorbent-coagulant by chemical treatment such as aluminum sulfate. The generated aluminium sludge was converted into adsorbent-coagulant by thermocatalytic and sequential chemical disposal. A thermocatalytic reactor with the temperature range from 400-700 C and with copper-chromium catalyst was applied to treat the aluminum sludge. catalyst was applied to treat the aluminum studge.

The resulting adsorbent-coagulant removed color up to 95% and chemical oxygen demand up to 75% from diluted kraft liquor. This method simultaneously solves sludge disposal problems and makes it possible to regenerate coagulant. (See also W91-11467) (Mertz-PTT) W91-11503

ACTIVATED SLUDGE TREATMENT OF KRAFT MILL EFFLUENTS FROM CONVEN-TIONAL AND OXYGEN BLEACHING. Tampere Water and Environmental District (Fin-

land) J. Nevalainen, P. R. Rantala, J. Junna, and R

Lammi.

Descriptors: \*Activated sludge process, \*Bleaching wastes, \*Chlorinated hydrocarbons, \*Kraft mills, \*Pulp wastes, \*Wastewater treatment, Chemical oxygen demand, Chlorinated aromatic compounds, Oxidation, Pulp and paper industry, Westewater enduring Wastewater analysis.

Conventional and oxygen bleaching effluents from hardwood kraft pulp mills were treated in labora-tory-scale activated sludge processes. The main interest was the fate of organochlorine compounds in the activated sludge process. In the treatment of conventional bleaching wastewaters the 7-day biological oxygen demand-reduction was 80-91% and in oxygen bleaching wastewaters 86-93%. The respective chemical oxygen demand removals were about 40% for conventional bleaching and 50% for about 40% to conventional teaching and 50% to oxygen bleaching. The adsorbable organic halogen reductions were on average 22% in the treatment of conventional and 40% in oxygen bleaching effluents. The reductions of chlorinated phenols, guaiacols, and catecols were usually more than 50% in both reactors. Very little accumulation of adsorbable organic halogens into the sludge was observed. The stripping of adsorbable organic halogens from aeration unit was insignificant. (See also W91-11467) (Author's abstract)

ANAEROBIC DEGRADATION OF PCP AND PHENOL IN FIXED-FILM REACTORS: THE INFLUENCE OF AN ADDITIONAL SUB-

anaerobic degradation of pentachlorophenol (PCP) and phenol was examined in two lab-scale fixed-film reactors. Anaerobic digested sewage inted-nim reactors. Anaeronic tigestees sewage sludge from a municipal treatment plant was used as inoculum. The reactors were fed a mineral medium containing PCP (1-2 mg/L) and phenol (4-6 mg/L). In addition one of the reactors received 1 g/L glucose as an easily degradable carbon source. After 6 months of continuous opercaroon source. After 6 monits of continuous operation, the removal of PCP in the reactor with no glucose added was approximately 60%, whereas the removal in the reactor with glucose reached 98%. Tetrachlorophenol and trichlorophenol were found as degradation products and the removal of these compounds was also significantly enhanced by the presence of glucose. Phenol degradation was approximately 70% with glucose added and 95% without glucose. Examination of the inert carrier in the two reactors showed that biofilm formation occurred primarily in the reactor receiving glucose as an addition carbon source. In this reactor the biomass was both an immobilized film and a sludge bed caught between the Raschig rings. In the reactor with no glucose, the biomass was concentrated in the sludge bed. QUALITY OF SALMONID HATCHERY EF-FLUENTS DURING A SUMMER LOW-FLOW SEASON.

Vashington State Dept. of Ecology, Olympia.

W. Kendra.

Transactions of the American Fisheries Society TAFSAI, Vol. 120, No. 1, p 43-51, January 1991. 3 fig, 4 tab, 21 ref.

Descriptors: \*Effluents, \*Fish hatcheries, \*Wastewater pollution, \*Wastewater treatment, \*Water pollution effects, \*Water pollution sources, Ammonia, Benthic fauna, Chemical oxygen demand, Hydrogen ion concentration, Invertebrates, Nitrogen, Nutrients, Oligotrophy, Permits, Phosphorus, Salmon, Sedimentation, Stream biota, Suspended solids, Temperature, Trout, Water quality standards

The quality of salmonid hatchery effluents and receiving streams in Washington State was assessed during the 1988 summer low-flow period. Relative to hatchery influent waters, effluents showed significant increases in temperature, pH, suspended solids ammonia organic pitrogen to period. suspended solids, ammonia, organic nitrogen, total phosphorus, and chemical oxygen demand. Wastewater discharges sometimes violated state water quality standards; effects were exacerbated by low dilution. Hatchery nutrient loads equaled or exceeded receiving water loads; effects of en-richment were most evident in oligotrophic waters. Benthic invertebrates sensitive to organic waste were often replaced by pollution-tolerant forms in the vicinity of hatchery outfalls. Hatchery torns in the vicinity of haterery outlants. Fractiery discharges to Scatter Creek provided phosphorus loading equivalent to secondarily treated sewage discharge from a town of 2,300 people, while phosphorus loading to Cinebar, Canyonfalls, and Issaquah Creeks corresponded to sewage effluent loads from communities of 900, 1,300, and 300 people, respectively. Stream invertebrates experienced moderate change upon exposure to hatchery ef-fluents, although altered communities largely recovered within 0.5 km downstream of a dis Results necessitated revision of existing hatchery wastewater discharge permits in Washington. Sedimentation of waste solids was stipulated as a minimum requirement, and phosphorus loading con-trols may be applied in fresh waters deemed sensitive to nutrient enrichment. (Doria-PTT) W91-11532

PRE-HYDROLYZED ALUMINUM HYDROX-IDE AND IRON HYDROXIDE IN ACTIVATED SLUDGE TREATMENT.

Pennsylvania State Univ., University Park. Dept. of Civil Engineering.

R. B. Bowen.

Water Pollution Control Association of Pennsylva-nia Magazine, Vol. 24, No. 3, p 10-14, May/June 1991. 7 fig, 1 tab, 5 ref.

Descriptors: \*Activated sludge process, \*Aluminum, \*Chemical precipitation, \*Iron, \*Wastewater treatment, Biological oxygen demand, Biological wastewater treatment, Chlorides, Hydrogen ion concentration, Hydroxides, Sludge volume index, Sulfates, Suspended solids.

Iron and aluminum are used in physical-chemical precipitation treatment of wastewater to remove colloidal organic material and inorganic phosphate. The use of iron and aluminum salts in biological activated sludge treatment was examined. The best treatment was obtained for reactors that received additions of metal hydroxides. Addition of metal additions of metal hydroxides. Addition of metal salts without prehydrolysis generally led to pH perturbation and thus did not result in improved removals of biological oxygen demand (BOD) and suspended solids (SS). Exceptions were lower effluent SS with 18 mg/L and 28 mg/L FeCl3 additions than the average SS for control reactors and an overall lower sludge volume index (SVI) and lower effluent BOD with the 28 mg/L A12/SCV43 addition than the average SVI and Al2(SO4)3 addition than the average SVI and BOD for the control reactors. The success of the Al2(SO4)3 addition may be due to the higher pH level that was maintained in its reactor relative to the pH of the other Al2(SO4)3 and FeCl3 addition the ph of the other AL(SO4)3 and Fe(L)3 addition reactors. Al(OH3) addition produced the lowest effluent BOD followed by Fe(OH)3 addition. However, the iron hydroxide reactors had lower effluent SS and a lower SVI than did the reactors with aluminum hydroxide added. The reactors with iron hydroxide at 3.5% of the mixed liquor

### Ultimate Disposal Of Wastes—Group 5E

suspended solids (MLSS) had effluent BOD and suspended solids (MLSS) and effluent BOD and SS lower than that for the reactor with iron hy-droxide at 7% of the MLSS. The reactor with 7% iron hydroxide had a lower SVI than the reactor with 3.5% iron hydroxide. It is concluded that addition of prehydrolyzed metal salts results in improved biological treatment. MANAGING TOXIC SUBSTANCES IN MUNIC-IFAL WASTEWATER TREATMENT PLANTS. Springettsbury Township Wastewater Treatment Facility, PA. M. A. Kyle.

Water Pollution Control Association of Pennsylva-nia Magazine, Vol. 24, No. 3, p 26-32, May/June 1991. 4 fig, 11 ref.

Descriptors: \*Municipal wastewater, \*Permits, \*Toxic wastes, \*Wastewater treatment, \*Water pollution control, \*Water quality standards, Administrative agencies, Legal aspects, Optimization, Pennsylvania, Technology, Wastewater facilities.

Faced with the requirement to meet stringent effluent limitations based on receiving stream quality for nonconventional pollutants (toxics), the municifor nonconventional pollutants (toxics), the municipal wastewater plant operator in Pennsylvania can attempt one or more of the following actions: (1) petition the state Department of Environmental Resources (DER) to relax the plant effluent limits; (2) remove the pollutants from the liquid stream after they enter the treatment plant; or (3) reduce the influence load of toxics entering the plant. the influence load of toxics entering the plant. Process control strategies to optimize toxics re-moval depends on the pollutant class. The first steps in developing a toxics control program are to determine if there is a 'toxicity' problem and to identify the specific compounds causing the prob-lem. In some cases, the DER may determine that the permittee does have a problem, and may re-quire a Toxics Reduction Evaluation (TRE) as part of the effluent discharge permit. The purpose part of the effluent discharge permit. The purpose of a TRE is to define the quantities of pollutants, identify their sources, determine their fates, and recommend control technologies that will control or eliminate them. By developing a toxics control program that includes the technical evaluation of proposed limits, the use of optimum treatment technology, and the control of industrial discontrology, and the control of industrial dis-charges, a publicly owned treatment works has a good chance of not experiencing passthrough of pollutants into receiving waters, or of having a permit violation. (Doria-PTT)

NEW STORM WATER REGULATIONS REQUIRE SIGNIFICANT COMPLIANCE ACTIONS BY BOTH INDUSTRIES AND MUNICI-

PALITIES.
BCM Engineers, Inc., Plymouth Meeting, PA.
K. Horstman, and J. Sartor.
Water Pollution Control Association of Pennsylvania Magazine, Vol. 24, No. 3, p 35-37, May/June

Descriptors: \*Permits, \*Regulations, \*Storm runoff, \*Storm water management, \*Urban runoff, \*Wastewater facilities, \*Water pollution sources, Costs, Enforcement, Land disposal, Pennsylvania, Storm sewers. Storm wastewater.

New storm water discharge regulations just published by the U. S. Environmental Protection Agency (EPA) could have a major impact on wastewater treatment plants in Pennsylvania. The regulations require municipal and industrial wastewater treatment plants to obtain storm water discharge permits and to implement measures to control pollutants in storm water discharges. Permitting and enforcement will be the responsibility of the Pensylvania Department of Environmental mitting and enforcement will be the responsibility of the Pennsylvania Department of Environmental Resources (DER) under the National Pollutant Discharge Elimination System (NPDES). The following facilities must comply: (1) facilities with a design flow greater than or equal to 1.0 million gallons per day; (2) facilities required to have an approved pretreatment program under 40 CFR Part 403; and 3) land application sites outside the confines of a treatment plant where sludge is not directly used for farmlands, domestic gardens, or

some other beneficial purpose. Both area-wide and site-specific storm water drainage systems are covered, and municipalities must prohibit nonstorm water discharges into their separate storm sewer systems. Permits will not be based on end-of-pipe effluent limits like wastewater permits but on the recommendations in the required management. emuent mints make wasteware permits out on the recommendations in the required management plan. By collecting accurate system information and carefully evaluating alternative control methods at the outset, municipal officials can help keep long-term costs to a minimum while ensuring the effectiveness of implemented measures. Descriptors: \*Aerobic treatment, \*Anaerobic digestion, \*Aquaculture, \*Wastewater treatment, \*Nitrites, \*Biological wastewater treatment, Nitrification, Trickling filters, Ammonia, Oxidation, Nitrogen fixing bacteria, Fluidized beds, Wastewater reactors, Biological treatment, Denitrification.

Biological oxidation and reduction of inorganic nitrogen were studied in an aquaculture unit equipped with an aerobic trickling filter and two, anaerobic, fluidized bed columns. The rate of ammonia oxidation in the trickling filter was shown to monia oxidation in the trickling filter was shown to be dependent on the ambient ammonia concentration in the unit, indicating that ammonia oxidation by the nitrifying bacteria was substrate-limited with respect to ammonia. The maximum removal rate of ammonia was 0.43 g NH4-N/sq m/d. Nitrite removal by the trickling filter took place when ambient ammonia concentrations were < 1 mg/L NH4-N, while at higher ambient ammonia centrations nitrite accumulated. The fluidized concentrations intrite accuminated. In mutuated bed columns, employed in the system, were fed with endogenous organic material from the pond. Under these conditions, high specific nitrate removal rates were obtained at relatively short retention times. Nitrate removal, however, fluctuated sharply over a diurnal cycle and nitrite accumulation took place under all running conditions examined. (Author's abstract)

DESIGN AND PERFORMANCE OF THE BIO-FISH WATER RECIRCULATION SYSTEM. Norsk Hydroteknisk Lab., Trondheim B. Eikebrokk.

Aquacultural Engineering AQEND6, Vol. 9, No. 4, p 285-294, 1990. 11 fig.

Descriptors: \*Water reuse, \*Wastewater treatment, \*Water conservation, \*Aquaculture, \*BIOFISH system, \*Recirculated water, \*Water treatment, \*Water supply, Design standards, Performance evaluation, Norway, Fish farming, Aeration, Biological treatment, Filtration, Nitrification, Oxygenation, Trout, Salmon, Water use, Ammonia.

Water is reused in aquaculture due to shortages in water quantity and quality, more stringent effluent quality standards, the need for energy conserva-tion, more intensive production regimes, and a better overall economy. Conventional water recirbetter overall economy. Conventional water recirculation systems are not, however, widely used in Norway, because current production regimes are not able to fully utilize the potential of recirculation systems, and the rather poor reputation of such systems due to complexities in both design and operation. These facts led to the initiation of a project to identify simple alternatives to the conventional water recirculation systems applied in fish farming. A simple intank water treatment and reuse system, called BIOFISH, was designed. The primary unit of the system is a submerged and aerated upflow biofilter, with nitrification and

oxygen transfer as the primary functions. In addition, the biofilter acts as an air lift pump, creating the necessary water circulation flow in the fish tank. Particles are removed from the effluent through a pipe from the tank bottom. The BIO-FISH system has been operated for several months; both with rainbow trout and Atlantic salmon smolt. Results show that water consumption, and thereby the amount of effluent water, can be reduced by 90-95% compared to flow through systems. The oxygen concentration in the fish tank was 5 mg/L or higher, and total ammonia-N concentration never exceeded 1 mg NH4(+)-N/L, even at fish densities as high as 80 kg/cu m. ENVIRONMENTAL ASSESSMENT OF WASTEWATER MARINE DISPOSAL OF XIAOGANG ZONE, NINGBO.

Tsinghua Univ., Beijing (China). M. Huang, Q. He, Z. Han, H. Chen, and X. Liao. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 443-447, 1991. 1 fig. 3 tab, 2 ref.

Descriptors: \*China, \*Environmental impact, \*Outfall, \*Path of pollutants, \*Wastewater disposal, \*Wastewater treatment facilities, \*Water pollution sources, Agriculture, Dissolved oxygen, Fer-tilizers, Mathematical models, Model studies, Nitrogen, Nutrient concentrations, Runoff, Water movement, Water quality, Water quality standards, Yongjiang River.

The Xiaogang Zone is located in the northeastern part of Ningbo, China. It encompasses an area of 3.9 sq km, and is designed to treat 40,000 cu m/day of wastewater. The mouth of the Yongjiang River is about 600 m from the zone. The average flow of the ebb tide at the river mouth is 520 cu m/sec, including 70 cu m/sec of runoff, which has a direct influence on the water quality of the nearby coast of the Xiaogang zone. The effluent from preliminary treatment is discharged at Changitaozui and distributed evenly into the ocean by diffusers up to 150 m offshore at a water depth of 15 m. Since the 150 m offshore at a water depth of 15 m. Since the nitrogen pollution in this area is rather serious, more consideration should be given to controlling the loss of fertilizer from the land. The allowable water quality concentrations in this area are set to COD-Mn below 4 mg/L and dissolved oxygen greater than 4 mg/L. Water quality models can predict water particle movement and increase of pollutant concentration. (Brunone-PTT) W91-10570

ASSESSMENT OF THE ENVIRONMENTAL CAPACITY OF ENCLOSED COASTAL SEA. Zagreb Univ. (Yugoslavia). Faculty of Civil Engi-S. Tedeschi.

### **Group 5E—Ultimate Disposal Of Wastes**

Wastewater discharge into the coastal sea is treat-ed wastewater, inflowing through coastal or marine outfalls. Three types of discharge site characteristics and the receiving marine environment are considered: the open sea in which strong cur-rents and exchange of the sea water mass exist; a semi-enclosed type (estuary or river mouth an channels, with a satisfactory exchange of sea mass, either due to the difference in salinity or density, or due to the influence of tidal exchange; or an enclosed sea system (lagoon or gulf), with a very limited sea mass exchange with the open sea. The assessment of environmental capacity is one of the tools for decision-making in the selection of measures for sea quality protection in semi-enclosed and enclosed coastal seas. When assessing the environmental capacity, all of the processes affecting the assimilation or accumulation of anthropogenic matter in the marine ecosystem should be taken into account. (Brunone-PTT)

A field-scale, pilot plant study of aerobic thermo-philic co-composting of digested, dewatered wastewater sludge together with ligneous cellulose wastewater studge together with ingerous cellulose residuals from paper mill and wine industries (poplar bark and grape vine stalks) was carried out in northern Italy. Mean temperatures above 55 C were reached after several days and were maintained throughout much of the composting cycle. The minimum recorded temperatures reached 55 C

for a few consecutive days near the beginning of the compost cycle. A decrease in pile temperature after each turning operation was followed by an after each turning operation was followed by an increase. By the end of the complete compost cycle, the concentration of fecal coliforms was reduced from 100,000/g dry matter to 10/gdm. Fecal streptococci were reduced from 1 million/gdm to 100/gdm. Salmonella were reduced to a very low level during the first days of composting and were not detected in a 100 g sample by the 83rd day. The mean C/N ratio of the mixture was reduced during composting from 25 to 17, indicating that complete composting with biological maturity of the materials was achieved. The product of composting was balanced from a nutritive eleof composting was balanced from a nutritive ele-ment aspect. Total humus content was high, conment aspect. Total humus content was high, con-sisting mainly of humic acids, products with long-lasting, slow-release soil fertility properties. Growth tests indicated that the compost had a positive effect on the development and production of crops. (Doria-PTT) W91-10693

Processing organic waste products into black soil and organic fertilizers, apart from the possibilities of incineration and dumping, is one of the alternatives for sludge processing. Measures to promote recycling in The Netherlands are stimulated by the government. For economic reasons, recycling merits maximum attention. On the basis of the fertilizer characteristics of purified sludge and other organic waste products (agro-industrial by-products), processing into fertilizer and soil are regarded as possibilities, provided the final product regarded as possibilities, provided the final product meets certain quality criteria. In The Netherlands standards are being developed for the basic soil quality and for organic fertilizers. By combining 'loaded' and 'unloaded' organic waste products, specified qualities of organic fertilizers and black soil are attainable. Black soil is obtained by mixing sandy soils with stabilized organic materials in order to obtain better structural properties for imorder to obtain better structural properties for im-proved growth conditions for landscaping. Stabiliaction of purified sludge takes place on natural drying beds and by composting in covered halls. The final composition is determined on the basis of available data by means of a computer projection. The black soil is applied in various green belt projects and the organic fertilizers are used in agriculture. (See also W91-10699) (Author's abstract) W91-10705

This is one of a series of reports that present methodologies for assessing the potential risks to humans or other organisms from the disposal or reuse of municipal sludge. The sludge management practices addressed by this series include land ap-plication practices, distribution and marketing proplication practices, distribution and marketing programs, landfilling, incineration and ocean disposal. In particular, these reports provide methods of evaluating potential health and environmental risks from toxic chemicals that may be present in sludge. This document addresses risks from chemicals associated with land application and distribution and marketing of municipal sludge. These proposed marketing of municipal sludge. These proposed risk assessment procedures are designed as tools to assist in the development of regulations for sludge management practices. The procedures are struc-tured to allow calculation of technical criteria for sludge disposal/reuse options based on the potential for adverse health or environmental impacts. The criteria may address management practices (such as site design or process control specifications), limits on sludge disposal rates or limits on toxic chemical concentrations in the sludge. Under the Marine Protection, Research and Sanctuaries Act, the US EPA has responsibility for establishing and applying criteria for reviewing and evaluating permits for dumping wastes into the ocean, and the US Army Corps of Engineers (COE) has responsibility for issuing permits for the disposal of dredged material into the ocean. After several years of operational experience, the EPA and the COE have reexamined the strengths and weaknesses of this remit program and the general weaknesses of this permit program and the general state of the art in sediment testing for the evaluastate of the disposal of dredged material into the marine environment. This paper describes a predic-tive hazard assessment strategy and decision ra-tionale for disposal that can be used as the basis for revisions both in the ocean dumping regulations and in the permitting program. The strategy requires the physical, chemical, and biological characterization of the dredged material and the dumpsite sediment. This characterization provides a sale sealment. This characterization provides a basis for developing a comprehensive, tiered test-ing and analysis program for determining the po-tential environmental exposures and biological ef-fects. The synthesis of the exposure and effects data supports an overall hazard assessment of the potential environmental effects, which in turn, forms the basis for an initial permitting decision. The disposal activity is monitored specifically to verify the prediction of hazard and to support future revisions of the permit requirements. The

### Ultimate Disposal Of Wastes—Group 5E

technical success of this program can be measured by the degree of agreement between the predicted and the measured environmental consequences of the open water disposal of Black Rock Harbor dredged material. Once evaluated, the hazard as-sessment research strategy can be used to provide the conceptual framework and criteria for the technical assessments that are an integral compo-nent of environmental management decisions. SURFACE DILUTION OF ROUND SUB-MERGED BUOYANT JETS.

Michigan Univ., Ann Arbor. Dept. of Civil Engi-

S. J. Wright, P. J. W. Roberts, Y. Zhongmin, and N. E. Bradley. Journal of Hydraulic Research JHYRAF, Vol. 29, No. 1, p 67-89, 1991. 12 fig, 2 tab, 22 ref.

Descriptors: \*Buoyant jets, \*Hydraulic engineering, \*Hydraulic jump, \*Jets, \*Outfall, \*Wastewater disposal, Flow equations, Flow models, Hydrodynamics, Mathematical analysis, Mixing, Radial flow.

Conventional analyses for estimating dilution within a submerged vertical round buoyant jet as it interacts with a free surface in an unstratified, stagnant receiving fluid generally consider only the mixing due to the rising jet and neglect further dilution in the region where the jet is deflected and begins to spread radially along the surface. A study begins to spread radiany along the surface. A study has been made of the entrainment within a region that typically extends a few flow depths away from the source. This region was analyzed as a radial internal hydraulic jump and computational results indicate dilution increases even greater than results indicate dilution increases even greater than within the submerged jet. Two experimental studies were performed to measure dilution within the radially spreading flow region. The data indicate that the surface dilution directly above the jet can be predicted by allowing for a thin blocking layer at the surface. The data also indicate a three to fivefold increase in surface dilution across the in-ternal jump. Both the analysis and data indicate a hydrodynamic instability for jets with low buoyan-cy that results in the gravitational layer locally mixing over the entire depth with some re-entrain-ment back into the internal jump. HYDROGEOLOGIC INFERENCES FROM DRILLERS' LOGS AND FROM GRAVITY AND RESISTIVITY SURVEYS IN THE AMARGOSA DESERT, SOUTHERN NEVADA.

Geological Survey, Denver, CO. W. J. Oatfield, and J. B. Czarnecki. Journal of Hydrology JHYDA7, Vol. 124, No. 1/2, p 131-158, April 1991. 17 fig, 18 ref.

Descriptors: \*Borehole geophysics, \*Geohydrology, \*Geological surveys, \*Geophysical surveys, \*Groundwater movement, \*Nevada, \*Radioactive waste disposal, \*Well logs, Geologic control, Geologic units, Gravity studies, Groundwater barriers, Hydrology, Resistivity, Solute transport, Underground waste disposal.

The Amargosa Desert of southern Nevada, in the Basin and Range geological province, is hydraulically downgradient from Yucca Mountain, the potential site of a repository for high-level nuclear waste. Groundwater flow paths and flow rates beneath the Amargosa Desert are controlled partly by the total saturated thickness and the hydraulic properties of basin-fill alluvial sediments. Drillers' logs of water wells completed in alluvium were analyzed to help desertation. logs of water wells completed in alluvium were analyzed to help characterize the hydrogeologic framework underlying the Amargosa Desert. Frac-

tions of coarse-grained sediments, calculated from tions of course-grained seuments, calculated from each of these logs, were contoured using a universal-kriging routine to interpolate values. Results from a previous electrical sounding survey also were contoured, including the estimated depth to basement rocks. The vertical electric sounding results were obtained from individual depth-to-resistivity profiles, from which the average resistivity of the total profile and the resistivity of the upper 75 m were calculated. The distribution and vari-75 m were calculated. The distribution and variations in regional gravity. Patterns of contours of the resistivity of the upper 75 m of alluvium were similar to patterns of regional contours of the predominant cation (sodium) in groundwater. Gravity lows correspond in some places to the presence of lacustrine, eolian, or marsh surface deposits, which may function as barriers to groundwater flow. Gravity lows also correspond to areas with thick basin-fill sediments, which was corroborated by depth-to-basement data determined from vertical electric soundings. Depths to basement rocks may be as much as 1600 m based on data from the resistivity survey, which were corroborated in part by seismic-refraction survey data. Small variations exist in the percentage of the corroborated in part by seismic-refraction survey data. Small variations exist in the percentage of the basin fill that is saturated. The unsaturated zone is always <15% of the alluvial column. Analysis of depth-to-water and hydrochemical data, in conjunction with average resistivity data for the upper 75 m of alluvium, suggest a hydrologic barrier near the center of the Amargosa Desert. A new European Community directive due to be implemented soon will make sludge disposal on agricultural land more difficult. When this measure agricultural land more difficult. When this measure is combined with growing objections to sea disposal and the limited possibilities for landfilling, alternative avenues of disposal for the growing quantities of sewage sludge are increasingly more important. Greater use of incineration is a possible suitable route. Other possibilities are agricultural use of sewage sludge, sludge dewatering and biological conditioning, and other thermal processes. Other topics discussed are sludge characterization and quality aspects. (See W91-11116 thru W91-11161) (Brunone-PTT)

The methods which the sewage sludge disposal authorities use to spread sludge on farmland must avoid environmental problems, provide service to farmers, and be cost-effective. Selection of the correct equipment and good business practices is essential to the longterm security of the agricultur-al outlet for sewage sludge disposal. However, all other for sewage studge usposa. Towever, studge spreading is still the major source of public complaint when compared with other aspects of sewage treatment. These complaints are due principally to real or perceived odor, and other environments. mental concerns relating to specific methods of sludge spreading, particularly the potential for disease transmission by aerosols, and ammonia volatilization with its potential impact on global soil acidification. Farmers are becoming increasingly acidification. Farmers are becoming increasingly aware of potential problems of soil structural damage through the use of heavy sludge spreading vehicles and the difficulty of spreading sludge evenly and at the target application rate, which has implications for crop response and soil monitoring. The cost-effectiveness of sophisticated equipment depends upon local operating conditions, however, not all of the developments in equipment design are of high cost and these may well be considered by the sludge disposal authorities. ### Group 5E-Ultimate Disposal Of Wastes

Four options are considered for utilizing sewage sludge on forest land as a resource, rather than in agriculture. Within the forestry cycle the follow-ing uses have been determined: as a soil condition er for the restoration of disturbed soils, as a soilforming material for reclaiming disturbed soils, as a soil-forming material for reclaiming derelict land, and for producing soil for use on green areas in the urban environment. The characteristics of the sludge, particularly organic matter, nitrogen re-lease, physical properties and hygienic status, are lease, physical properties and hygienic status, are modified by treatment and must be appropriate to the end use. To successfully exploit the resource potential of sewage sludge requires planning, management and cost-effective transport and applica-tion of the sludge. Planning is necessary for the tion of the studge. Planning is necessary for the protection of water resources, such as avoiding private supply catchments in forests, and the coordination of sludge production/storage with irregular/spasmodic demand as in reclamation schemes. Application rates and timing must be schemes. Application rates and timing must be appropriate for the site conditions to avoid polluting runoff. Sludge application methods may differ from those appropriate for agricultural use and may require the development of new equipment or working methods. (See also W91-11115) (Brunone-DTT). Soil and plant samples from several locations in Germany were analyzed in a joint project with samples from trials with dressings of sewage sludge between 1959 and 1980. Chlorinated hydrocarbon did not accumulate in the soils or transfer to plants. did not accumulate in the soils of transfer to plants. Polychlorinated biphenpls increased on an average 5-fold to 17-fold and polycyclic compounds 5-fold and 10-fold after application of sewage sludge. No regular transfer to crop plants was detectable, where the order of magnitude was in the microg/kg range. The results showed, with a high degree of certainty, that the organic substances investigated do not need to be limiting factors for the use of sewage sludge in agriculture. The amount of sewage sludge and the problems with disposal are increasing. Because of the decreasingly available areas for ultimate disposal and use in agriculture (possible contamination with organic substances and heavy metals), the inciner-ation of sewage sludge will receive more impor-tance. Quantitative data on the formation of diox-ins and furans for sludge incineration are limited. ins and turians of studge incineration are infinited. The formation of these compounds in studge incineration plants is lower than the emissions from incineration of municipal waste, the emission of dioxins and furans are normally lower than the legislative limit values. The formation of dioxins registative limit values. In elormation of dioxins can be reduced by the process condition in the incinerator or by addition of lime to the incineration process. Dioxins and furans are found primarily in the fly ashes and gases. Minimization of these my in the fly saines and gases. Millimization of these emissions can be achieved by high burn out of the fly ash, low copper content, and low residence time of fly ash in critical temperature zones. Netherlands, \*Wastewater treatment, Chemical oxygen demand, Heavy metals, Hydrogen ion con-centration, Sludge drying.

The total quantity of sludge produced in the Netherlands is about 400,000 tons dry matter, of which about 25% is landfilled. Normally, sludge is landfilled together with other wastes. In a survey of 30 existing landfill sites, the quantity of sludge being landfilled does not exceed 10% of total waste composition. An effect of sludge on leachate quality could not be found with regard to heavy metals and some classical parameters (COD, Cl, etc.). Due to the relative low contribution of polluting components from sludge to the total quantity of polluting components in the landfilled waste, a major influence was not to be expected. Sludge polluting components in the landfilled waste, a major influence was not to be expected. Sludge was applied to other wastes in larger quantities (24%, with 38% dry matter). Sludge did have an influence on the leachate quality, i.e. lower COD and volatile fatty acids (VFA) concentration and higher pH. As a result of the higher pH value, heavy metal concentrations were diminished. In the long-term, the difference will probably disappear, and COD, VFA and pH will be equal after stabilization. Descriptors: \*Agriculture, \*France, \*Landfills, \*Regulations, \*Sludge disposal, \*Sludge treatment, \*Sludge utilization, \*Wastewater treatment, Com-parison studies, Heavy metals, Sludge drying.

Agricultural use of sewage sludge is a priority of French disposal policy. With estimated current production of 600,000 tons dry matter per year, the production of 000,000 tons ory matter per year, the proportion used in agriculture has increased from 20 to 30%, to 40 to 50% over the last ten years while landfilling has declined. In particular, the various constraints (heavy metal contamination, low dry matter content, etc.) are now relevant to low dry matter content, etc.) are now relevant to every sludge disposal option (agricultural use, landfilling, incineration). The true costs of disposal must increasingly be paid; actions must be taken to enable the full potential of agricultural use to developed; and effective solutions have to be tai-lored to individual cases and should be more closely adapted to the local context. The application of sludge to agricultural land in liquid form will probsludge to agricultural land in liquid form will prob-ably remain the best solution in both practical and economic terms for the great majority of small sewage treatment plants. The medium and large plants will develop solutions based on improved complementarity, depending on local constraints and opportunities: between sludge treatment and final disposal; between different sludge disposal options; and between disposal of sludge and of other wastes. MODIFICATIONS OF SOME PHYSICAL PROPERTIES IN TWO COMPOST-AMENDED ITALIAN SOILS.

Consiglio Nazionale delle Ricerche, Pisa (Italy).

Ist. di Chimica Terreno. G. V. Guidi, R. Pini, and G. Poggio.

G. V. Outdi, K. Pini, and G. Poggio. IN: Sewage Sludge Treatment and Use: New Developments, Technological Aspects and Environmental Effects. Elsevier Science Publishing Co., New York. 1989. p 427-432. 2 fig, 2 tab, 4 ref.

Descriptors: \*Composting, \*Fertilizers, \*Italy, \*Sludge disposal, \*Soil amendments, \*Soil physical properties, \*Wastewater treatment, organic matter, Soil chemistry, Soil porosity.

Two field experiments were conducted in which different rates of composts were compared with farmyard manure and mineral fertilizers. Dressings rarmyard manure and mineral tertifizers. Dressings were applied yearly in one case on the basis of available nitrogen (100 kg/ha, 200 kg/ha, and 300 kg/ha) and in the second case on organic matter (15 tons/ha and 40 tons/ha). Large seasonal variations were found for water stability index and ations were found for water stability index and porosity. The effects of composts were similar to those of manure or sometimes higher, at corresponding rates. The addition of organic materials did not always improve soil physical characteristics immediately. Soil structural improvements were always related to the addition of organic matter. Crushed glass present in composts accumulated in the plough layer. The two soils different reactions to the repeated additions of high amounts of organic matter was probably due to physical parameters related to soil structure which could have been influenced more by inorganic binding agents than by the organic ones. In addition, some external physical stresses, such as rain, could have played a role in the mechanisms which regulate the played a role in the mechanisms which regulate the formation and the maintenance of soil pores of a given radius. Descriptors: \*Composting, \*Sludge disposal, \*Sludge utilization, \*Wastewater treatment, Aero-bic digestion, Disinfection, Dry matter, Organic matter, Sludge filters, Sludge stabilization.

The availability of organic solid waste materials has resulted in the composting of dewatered sewage sludges by closed or windrow systems with forced or spontaneous aeration. A new method of aerobic stabilization for the solid state of method of aerobic stabilization for the solid state of raw sewage sludge in the form of filter cake (20% to 22% of dry matter) has been developed that does not require bulking agents or mixing with other organic solids. These additives were neces-sary to overcome physical barriers to self-heating due to the high water content and to the low due to the high water content and to the low carbon-nitrogen ratio. In the new method the sludge is treated in a rotary tank supplied with pure oxygen, and the sludge quickly reaches (<12 hours) sanitizing temperatures (>60 C). Microbiological changes occurring during the process that are particularly important are sludge conditioning, sludge stabilization and disinfection. (See also W91-11115) (Author's abstract)

USE OF SEWAGE SLUDGE ON AGRICULTURAL LAND: IMPACT ON SOIL FAUNA.

Soil fauna maintain the long-term fertility of inten-Soil launa maintain the long-term fertility of intensively cultivated land. The pedofauma contribute to the humification of organic matter and the preservation of soil structure. Therefore, knowledge of the reaction of soil fauna to the application of sewage sludge as fertilizer is essential. The impact of liquid sewage sludge (LSS) was tested on macroinvertebrates between 1983 and 1986 using a variety of applications to humus-rich soils: LSS only, manure only, LSS and manure mixture, and only, manure only, LSS and manure mixture, and mineral fertilizers. Approximately 190,000 macroinvertebrates were captured and identified. The results show that LSS has an overall enrichment effect on the soil fauna; the decomposers, particularly the Diptera, benefit both in species richness and overall abundance. The increase in the numbers of decomposers (as potential prey) benefits the predator and parasite communities. The LSS plus manure mixture is the best treatment since both microdecomposers and macrodecomposers benefit. (See also W91-11115) (Brunone-PTT) W91-11150

EFFECTS OF SEWAGE SLUDGE AND WASTE COMPOST ON SOME SOIL ENZYMATIC ACTIVITIES TESTED IN A FIELD EXPERIMENT. Landwirtschaftlich-chemische Bundesanstalt, Linz

(Austra).

K. Aichberger, and R. Ohlinger.

Descriptors: \*Composting, \*Enzymes, \*Sludge disposal, \*Soil chemistry, \*Waste disposal, \*Wastewater treatment, Biomass, Carbon, Fertilization, Nutrient concentrations, Organic matter, Soil respiration.

In a field trial the effect of several year's application of heavy metal contaminated sewage sludges and waste composts was tested on some soil enzy-matic parameters. During the test period, high rates of organic matter, nutrients up to more than

1000 kg/ha and variable amounts of heavy metals were supplied. Mostly soil respiration, biomass carbon, dehydrogenase and protease activity were increased by waste application. No effects were noted for glucosidase and urease activity and phosphorus was depressed on the highest waste-treated plots. Altogether, sewage sludge and waste compost fertilization improved the soil enzymatic activities in 41% of all observations (n=234), but had no effect for 51% and depressed activities in only no effect for 51% and depressed activities in only 8% of all cases. EXISTING CONDITIONS FOR AGRICULTUR-AL UTILIZATION OF SEWAGE SLUDGE COMPOST IN JAPAN.

Japan Sewage Works Agency, Tokyo. Research and Technology Div.

In: Sewage Sludge Treatment and Use: New Developments, Technological Aspects and Environmental Effects. Elsevier Science Publishing Co., New York. 1989. p 451-463. 3 fig. 4 tab.

Descriptors: "Agriculture, "Compost marketing, "Composting, "Fertilizers, "Heavy metals, "Japan, "Sludge disposal, "Sludge utilization, "Wastewater treatment, Marketing, Odors, Questionnaires, Soil amendments, Workability.

To obtain basic data for formulating the marketing strategy of sewage sludge compost, a macroscopic study of competing fertilizers has been conducted with respect to their production, consumption and marketing. Outputs of the soil conditioners and compost (which accounts for the greater part of special fertilizers) are growing in recent years. Commercial compost which has fertilizing and soil Commercial compost which has retrilizing and soil conditioning effects will be the most likely competition. The position of sewage sludge compost has been identified in the market and promoting strategies have been planned. Four areas differing in climate and farming structure were selected for the climate and farming structure were selected for the survey. The questionnaire survey on the evaluation of sewage sludge compost and buying intentions of users showed that low price is important. The upper retail price limit for a 20 kg bag of sewage sludge compost seemed to be about 500 yen. Complaints were made about workability and odor. Sewage sludge compost should be available in pelleted forms or enriched with additives to differentiate it from other fertilizers. (See also W91-1115) (Authors) extends. 11115) (Author's abstract) W91-11152

PRODUCTION OF COMPOST FROM SEWAGE SLUDGE IN TOKYO. Tokyo Sewerage Bureau (Japan).

M Saika

M. Saika. In: Sewage Sludge Treatment and Use: New Developments, Technological Aspects and Environmental Effects. Elsevier Science Publishing Co., New York. 1989. p 464-472. 8 fig. 2 tab.

Descriptors: \*Composting, \*Incineration, \*Japan, \*Landfills, \*Sludge disposal, \*Sludge drying, \*Sludge treatment, \*Sludge utilization, \*Waste disposal, \*Wastewater treatment, Agriculture, Fermentation, Horticulture, Land disposal, Soil amendments, Urban planning.

The present sewerage service rate in Tokyo is 82%. The treated effluent averages about 5,050,000 cubic m, which results in approximately 114,000 cubic m of sludge each day. The sludge is dewatered and mostly incinerated and finally disposed of in landfill. With urbanization, sites for landfill have become difficult to find. To solve this prob-lem, the Tokyo Metropolitan Government has lem, the Tokyo Metropolitan Government has been conducting a variety of research project and experiments. A pilot plant for composting was constructed to find practical measures of sewage studge utilization at Minamitama Wastewater Treatment Plant in 1977. After two years of pilot plant study, a full-scale plant was constructed, which has been operating since 1980, with four transversal fermentation tanks and a stirring-turning machine. The plant has the capacity of producing 3 tons of compost a day from 8 tons of sludge.

### Group 5E-Ultimate Disposal Of Wastes

As no additive is needed, the mass of sludge does not increase in size. The fermenting process takes only 10 days. Produced compost is effective not only as a nitrogen fertilizer but also as a soil conditioner. When the compost came onto the market in 1980, farmers bought most of it, but horticulture has now increased the demand. (See also W91-11115) (Author's abstract)

BENEFICIAL UTILIZATION OF INCINERATED ASH AND MELTED SLAG. Public Works Research Inst., Tokyo (Japan).

Y. Ohshima.

 Sewage Sludge Treatment and Use: New Developments, Technological Aspects and Environmental Effects. Elsevier Science Publishing Co., New York. 1989. p 473-492. 11 fig. 10 tab, 3 ref.

Descriptors: \*Incineration, \*Japan, \*Sludge disposal, \*Sludge treatment, \*Sludge utilization, \*Wastewater treatment, Cost analysis, Economic aspects, Land disposal, Land reclamation, Sludge thickening.

Sewage sludge production in Japan was about 1.2 million tons in terms of dry solids per year in 1985, which is equivalent to about 75 g per capita per day. Sludge production has been increasing by more than 50,000 tons per year, corresponding to the construction of new wastewater treatment facilities throughout Japan. Most of the sludge is currently disposed of in Jandfills, including constal currently disposed of in landfills, including coastal land reclamation, but suitable sites for landfill are land reclamation, but suitable sites for landfill are becoming increasingly difficult to find, especially around large cities. Reduction of the sludge volume to be disposed, therefore, is a primary concern. About 55% of the sewage sludge in Japan is currently incinerated while melting processes are being scrutinized for reduction of volume for dis-posal and the utilization of melted slag. Utilization of the sewage sludge, including incinerated ash and melted slag for beneficial nurposes is another melted slag for beneficial purposes is another avenue of research. Utilization of incinerated ash and melted slag will greatly reduce the total cost of sludge treatment and disposal. (See also W91-11154 (Author's abstract)

Sewage sludge and liquid manure have high nitro-gen and phosphorus contents. Therefore, their use in agriculture can lead to nitrate problems in groundwater. Since the use of sewage sludge on land is the best disposal method, a combination of both sludge and manure could be a solution. In studies using a variety of plants and soil types only 50% of the total nitrogen was effectively utilized by the plants; the water soluble phosphorus was fully available, the organically bound phosphorus only partly; and the potassium was water-soluble in all three liquid manures. When liquid manure is applied, the amount of nitrogen is limited because of nitrate leaching. After consideration of all the aspects of a combination approach, fertilizing with a mixture of liquid manure and sevence shote is a mixture of liquid manure and sewage sludge is less desireable from the financial aspect, but better from an ecological perspective. The concentration

of plant nutrients in a mixture of liquid manure and odge is not optimal for all plants, but may be pplemented by specific mineral fertilizers. (See so W91-11115) (Brunone-PTT)

Physicochemical and biological measurements have been taken on soil samples from a long term field experiment in France on an acid coarse sandy soil to confirm and explain the intensive loss of a sludge organic matter added at moderate rates (10 tons/ha/year). The comparison between the farm yard manure (FYM) application and sewage sludge (SS) application showed that sludge is more readily mineralized, while the FYM treatment is able to sustain a high microbial biomass for a long time. The SS addition induced a higher increase in biological activities in the first stages of decomposion, but this stimulation was more transient than r FYM. This phenomena is probably due as much to the light textured soil and climatic influmuch to the ignt textured soil and climate intui-ences (more conducive to mineralization than to humification) as to the effect of the sludge bio-chemical composition on the microbial biomass size and activities. Descriptors: \*Fertilizers, \*Nitrogen, \*Sludge utilization, \*Slurries, \*Soil amendments, \*Wastewater treatment, Bandspreading, Comparison studies, Experimental design, Shallow injection, Splashplates.

Average cattle and pig slurry contains 4 to 4.5 kg N/ton. The efficiency of utilization of slurry N and sewage sludge N, compared with fertilizer N, has been found to be affected by weather conditions at spreading, the degree of dilution of the slurry with water, the rate of slurry application, and the amount of grass cover. The efficiency of slurry spreading methods on slurry N utilization by gradland was determined in randomized block fie experiments with six replications. Methods compared were the normal splashplate method, shallow injection, and bandspreading. The splashplate method produced little response. High yields of silage dry matter were obtained from shallow in-jection and bandspreading slurry applications. The bandspreading method was superior to the shallow injection method on permanent pasture. Bands-preading also requires little additional equipment. (See also W91-11115) (Brunone-PTT) W91-11161 method produced little response. High yields of

In 1984 the Oregon Agricultural Chemicals Asso-ciation (OACA) began to develop a program for the collection of used pesticide containers. The program was called the Oregon Pesticide Contain-er Initiative. The overall objective of this effort was to develop a simple program which took empty containers out of circulation thus preventing reuse or open storage. Initially the program was funded by the National Agricultural Chemical Association but in ensuing years it has been managed by the OACA and funded by that group. In order by the OACA and funded by that group. In order to make the program work a Chairperson and a Committee were needed who would educate growers regarding proper disposal, man receiving stations, and donate time and equipment. The Oregon Department of Environmental Quality developed the legal framework and procedures that would be used in the program. The program also required recyclers who would handle the containers and maintain strict control of those containers until they were disposed of Growers also needed. until they were disposed of. Growers also needed to recognize the hazard and potential liability of to recognize the hazard and potential liability of improperly stored pesticide containers. The program involved three main areas: education, collection, and disposal/recycle. Growers were instructed in the use of good triple rinse and container preparation techniques. Collection of the containers required dedication by a large number of volunteers. Collection sites were provided by local dealers. Dumpsters or lined trucks are used to collect the containers. Finally, all containers go to a recycler. Scripter Steel a power separator or a a recycler, Scnitzer Steel, a power generator, or a landfill. In one year, 92% of the containers were recycled or used for power generation. (See also W91-11162) (Korn-PTT) W91-11192

MINNESOTA WASTE PESTICIDE COLLEC-TION PILOT PROJECT.

In 1987 the Minnesota State Legislature funded a In 1987 the Minnesota State Legislature tunged a waste pesticide collection pilot study because of growing concern about the difficulties associated with the proper disposal of waste pesticides. The goals of the pilot study included an assessment of the types and quantities of waste pesticides cur-rently in the state, the collection and proper dis-

### Ultimate Disposal Of Wastes-Group 5E

posal of waste pesticides through temporary col-lection sites, and the definition of short and long term waste pesticide management needs. The project was implemented in two phases. The first phase consisted of a statewide mail survey directed project was implemented in two phases. The first phase consisted of a statewide mail survey directed at pesticide dealers, farmers, and user/applicators. The overall response rate was 77% which implied that the target audience thought the issue important enough to respond. The second phase of the pilot study involved the actual waste pesticide collections. A total of 5 individual waste pesticide collections were held with assistance from the local community. While some of the collections were free, others included fees to help pay the cost of disposal. The collection process allowed for the solids to be lab packed and the liquids consolidated. The empty containers generated from the consolidation of liquids were triple rinsed with the rinsate being managed as a hazardous waste, and the rinsed containers being disposed of as solid waste at local landfills. The pilot study proved to be a success and current plans include the preparation of recommendations and strategies that address the management of waste pesticides including both the historical problem and alternative actions for the prevention of future accumulations. (See also W91-11162) (Korn-PTT)

## URBAN PESTICIDE WASTE MANAGEMENT: STRATEGIES FOR EDUCATION AND COL-

LECTION.

S. M. Ridgley.

IN: Agrichemicals and Groundwater Protection:
Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 333-339, 1 tab, 10 ref.

Descriptors: \*Hazardous waste disposal, \*Minnesota, \*Nonpoint pollution sources, \*Pesticides, \*Urban areas, \*Waste disposal, \*Water pollution control, Cost sharing, Education, Feasibility studies, Public participation, Regulations, Surveys.

As a result of concerns about public health and environmental fate of waste pesticides and other household hazardous waste, a number of programs have been developed around the country. Since the fall of 1985 the Minnesota Pollution Control Agency (MPCA) has been conducting a household hazardous waste (HHW) collection and education program. Initially a nitot study was undertaken in program. Initially a pilot study was undertaken in which 14 collection projects were conducted. Detailed inventories were conducted at the pilot coltailed inventories were conducted at the pilot col-lection projects, resulting in valuable information concerning the types and quantities of HHW being stored in Minnesota homes. Pesticides were a common waste, although in comparison to paint and used oil the total volumes were much lower. The primary result of the pilot project was a piece of legislation passed in 1987, which authorized the MPCA to set up a permanent HHW program. The HHW program is responsible for the development and distribution of educational and technical mate-rials, including, general public information, and inand distribution of educational and technical mate-rials, including general public information and in-formation targeted towards specific audiences, such as children. In addition, the HHW program is also responsible for the development and operation of HHW collection sites, including support for one-day collection projects, as well as the estabishment of permanent, ongoing facilities. The MPCA'a HHW program is designed to be an investment in prevention. The responsibility for the management of these wastes lies jointly with the state and the local units of government. Therefore, costs are split 50/50. Ultimately, the responsibility for waste management lies with the average citizen-hence, the program's emphasis on education and waste reduction techniques. WASTE DISPOSAL FACILITIES AND COM-MUNITY RESPONSE: TRACING PATHWAYS FROM FACILITY IMPACTS TO COMMUNITY

Alberta Univ., Edmonton. Dept. of Civil Engineering.

C. Zeiss, and J. Atwater.

Canadian Journal of Civil Engineering CJCEB8, Vol. 18, No. 1, p 83-96, February 1991. 4 fig, 8 tab,

Descriptors: \*Environmental impact, \*Landfills, \*Municipal wastes, \*Public opinion, \*Public participation, \*Waste disposal, Attitudes, Management planning, Noise, Nuisance, Odors.

Host communities often very strongly oppose municipal waste disposal facilities despite the absence of very serious physical impacts. To effectively manage facility impacts and siting process and to reduce host community opposition, waste management engineers and planners must understand the linkage between physical impacts and beliefs and the resulting attitudes in the host community. Physical impacts, community beliefs, and attitudes were assessed at two typical waste facilities. Physical impacts, community beliefs, and attitudes were assessed at two typical waste facilities: a landfill and an incinerator for municipal solid waste. Typical landfill impacts consist of water and air quality effects, odors, noise, and visual impacts, incinerators generate air quality impacts, visual, and noise effects. While residents' general beliefs about facility impacts focus on obvious physical impacts (noise, odor, air emissions), residents' opinions of specific facilities comprise a broader set of physical and nonabysical impacts including prophysical and nonabysical and nonabysical and nonabysical and nonabysical impacts in prophysical and nonabysical and nonabysical impacts in prophysical and nonabysical impacts in a prophysical and n objection technics compiles a footest set of objective data of the sure to obvious nuisance impacts and correlate strongly with residents' attitudes about the facility. Therefore, impact management efforts will be effective if they, first, correctly identify underlying concerns and, then, manage the physical impacts that trigger them. (Author's abstract) W91-11280

### ASSIGNMENT OF THE CLASS OF HYDRAU-LIC-FILL WASTE DUMPS,

V. G. Panteleev.

Hydrotechnical Construction HYCOAR, Vol. 24, No. 6, p 362-369, December 1991. 3 tab. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 6, pp. 9-13, June, 1990.

Descriptors: \*Hydraulic fill, \*Mine wastes, \*Waste dumps, Classification, Design criteria, Dump failure, Mathematical equations, Soviet Union, Standard, Section 19

Hydraulic-fill dumps throughout the world have been known to fail, resulting in loss of life and disastrous pollution of the environment. Based on disastrous pollution of the environment. Based on recorded failures of tailings dumps in various parts of the world and other data, a multi-parameter system was devised for classification of hydraulic fill dumps. The class of a given hydraulic fill dump can be calculated by a formula that incorporates the following statistics about the dump: length of embankments; volume and mineralization of water settling in the pool; qualifications of specialists; degree of cascade character of construction; and degree of cascade character of construction; and location of buildings and structures in the zone of a possible dam-break wave. The method proposed here makes it possible to classify hydraulic-fill dumps uniformly regardless of which department within the Soviet Union was responsible for their construction. This is necessary because the standards and procedures offered by the various departments differ in the way they classify such structures. Besides standardizing classification, the new they despond the procedure of the processor of the proce method also will make it possible to improve the attitude of design, construction, and operating organization in relation to these structures. NITROGEN DYNAMICS OF PULP AND PAPER SLUDGE AMENDMENT TO FOREST

Washington Univ., Seattle, Coll. of Forest Resources. C. L. Henry.

Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 417-425, 1991. 2 fig, 6 tab, 12 ref.

Descriptors: \*Fate of pollutants, \*Forest soils, \*Land disposal, \*Nitrogen, \*Pulp wastes, \*Sludge utilization, \*Soil amendments, \*Waste utilization, Fertilizers, Forests, Nutrient removal, Plant growth, Primary sludge, Pulp and paper industry, Secondary sludge, Soil chemistry.

The use of pulp and paper sludge as a forest soil amendment was investigated. The fate of nitrogen added from field applications of pulp and paper sludge was determined. Primary sludge was found to immobilize small amounts of N, whereas secondary sludge mineralized over 70% of the N over a 21 month period. A large portion (39-82%) of the mineralized N was not accounted for by uptake, soil storage and nitrate leaching, and was assumed to be gaseous losses. Growth response from pulp and paper sludge amendments was measured. Surface application of primary sludge apparently had a beneficial mulching effect, as growth was 52-131% greater than in control soils. Addition of N to primary sludge resulted in growth 151-223% greater than in controls. Secondary sludge surfaceapplied resulted in excellent growth compared to controls (112-319% greater). HAZARD ASSESSMENT RESEARCH STRATE-GY FOR OCEAN DISPOSAL

### Group 5E—Ultimate Disposal Of Wastes

Environmental Research Lab., Narragansett, RI. J. H. Gentile, V. J. Bierman, J. F. Paul, H. A. Walker, and D. C. Miller. Available from the National Technical Information Service, Springfield, VA. 22161, as PB90-134388. Price codes: A03 in paper copy, A01 in microfice. Report No. EPA/600/D-89/231, 1989. IN: Oceanic Processes in Marine Pollution, Volume 3, Robert E. Krieger Publishing Co., Malabar, Florida, 1989. p 199-212, 14 fig. 1 tab, 17 ref.

Descriptors: \*Ocean dumping, \*Waste disposal, \*Risk assessment, \*Water pollution effects, Sludge disposal, Biological studies, Case studies, Long Island Sound, Statistical analysis, Model studies.

The hazard assessment research strategy is a proc ess which provides the necessary data and the predictive and interpretive framework for estimating the probability of harm to the environment. This strategy contains several components, each of which involves acquisition and synthesis of information leading to a regulatory decision. The objective of this strategy is to produce a systematic, scientifically sound basis for estimating the probability of any potential impact of waste contaminants on marine environments, forming the basis for an ultimate disposal decision. Two case studies were used to illustrate how a hazard assessment strategy synthesizes exposure and effects information to provide a causal linkage between mass inputs of contaminants and biological effects. The first study examines sewage sludge disposal at Deepwater Dumpsite-106. This was chosen as an example of how exposure fields for sludge contaminants can be generated with simple probabilis-tic models and how exposure and effects information can be synthesized to predict the relationship between mass inputs of contaminants and biologi-cal effects. For polychlorinated biphenyls, the maximum predicted environmental concentrations outside the dumpsite for the low-mixing and highousside the uninpact for the row-maxing and ingi-mixing cases were 0.06 and 0.019 ng/L, respective-ly, at least two orders of magnitude lower than the water quality criterion value of 5 ng/L, which in turn represents a no-effect concentration. Thus, the turn represents a no-enect concentration. Thus, the probability of hazard is not particularly high, although the hazard to a percentage of organisms affected cannot be accurately determined. The second study, which examines the disposal of dredged material in a shallow coastal site in central Long Island Sound, is a field verification program designed to test methodologies required for the acquisition of exposure and effects information. Both the laboratory and field data are synthesized to evaluate the accuracy and confidence of predic-tions of the individual methods, the tiered hierarchal concept, and the final prediction. ### 5F. Water Treatment and **Quality Alteration**

SPECIAL REPORT: WATER SUPPLY AND SANITATION.

Bulletin of the Pan American Health Organization BPAHA3, Vol. 25, No. 1, p 87-96, 1991.

Descriptors: \*Developing countries, \*Drinking water, \*Sanitation, \*Water supply, \*Water treatment, Aquaculture, Cost analysis, Health effects, Irrigation, Latin America, Monitoring, Municipal wastewater, Surveys, Wastewater disposal, Wastewater treatment, Water quality control,

The United Nations Water Conference, held at Mar del Plata, Argentine, in 1977, recommended that 1981-1990 be designated the International Drinking Water Supply and Sanitation Decade. The purpose of the Decade was to provide a safe and adequate supply of drinking water as well as and adequate supply of drinking water as well as basic sanitary facilities to all people by 1990. During that Decade, the percentage of the urban population served by sanitary excreta disposal sys-tems increased from 78-80%; however, the actual number of people without such service also in-creased, by 7.6 million. Most countries have water quality surveillance and control programs in urban areas, and many have programs in rural areas. Surveillance programs are often, unfortunately, in-effective or only partially implemented. Surveys suggest that 75% or more of the water supply systems either did not provide effective disinfec-tion or had operational problems that interfered with it. In peripheral urban areas, the quality standards set by the countries were often not met and water use was generally inefficient, with losses as high as 60% of the water produced. 1988 data as high as own of the water produced. 1986 data indicate that wastewater from only 5-10% of urban households connected to water and sewerage receives treatment. Municipal wastewater can become an economically valuable resource when it become an economically valuation resource when it is reused for irrigation and aquaculture. However, uncontrolled use of untreated wastewater for irrigation poses health hazards. Investments made during the Decade were substantially less than the totals proposed for meeting established goals, due to the impact of external debt and inflation. Another Regional Conference on Water Supply and Sanitation, was held in September, 1990 in San Juan, Puerto Rico. A hundred participants representing 23 countries and external support agencies met to examine achievements. Strategies of international and bilateral and support for the formulation and execution of national programs were examined. (Mertz-PTT) W91-10482

#### LESSONS LEARNED FROM A THIRD WORLD WATER AND SANITATION PROJECT.

T. Jenkins-McLean. Journal of Environmental Health JEVHAH, p 34-38, Spring 1991. 2 fig, 4 ref.

Descriptors: \*Belize, \*Community development, \*Developing countries, \*Public health, \*Sanita-tion, \*Water supply, Education, Municipal wastewater, Public participation, Water quality, Water supply development.

In 1985, the United States Agency for International Development signed a contract with the Pragma Corporation to provided technical assistance to the Government of Belize. The goal of the water and sanitation component of the project was to ensure an adequate and safe water supply to 90% of the rural population in three districts; to provide larural population in three astracts; to provide in-trines or sanitation technologies to ensure 50% coverage of the districts; and to establish a rural water supply laboratory facility to monitor water quality. Community participation was the key to successful implementation of the project. Greater community participation was achieved when limited local resources were complemented by external resources. Educational campaigns concerning community development increased participation. For success, the village should express a genuine desire for the project and agree with the goals set cooperatively. Decentralization of government bureaucracy made the programs more accessible at the community level. Throughout the project, community ownership of the water and sanitation systems must be stressed to encourage improved maintenance of the systems. Advantages and disadmaintenance of the systems. Advantages and disad-vantages of the different types of water and sanita-tion systems must be thoroughly explained to enable community members to understand the ap-propriate technology. The job of the project staff is to make realistic assessments for available re-sources and labor contributions. If women were fully involved in decisions to improve household sanitation, they would be better able to educate their families in practices that improve health and hygiene. In communities with longstanding tradi-tions of cooperative work endeavors, mobilization of community members required less effort from the project staff and village leaders. (Mertz-PTT)

### HEALTH-RELATED WATER MICROBIOLO-

For 1990. Proceedings of an international symposium organized by the International Association on Water Pollution Research and Control Specialist Group on Health-Related Water Microbiology held in Tuebingen, Germany, 1-6 April 1990. Water Science and Technology WSTED4, Vol. 24, No. 2, 1991. 433p. Edited by W. O. K. Grabow, R. Morris, and K. Botzenhart.

Descriptors: \*Conferences, \*Drinking water, \*Epidemiology, \*Microbiological studies, \*Public health, \*Risk assessment, \*Water pollution, \*Water quality monitoring, \*Water supply, Analytical methods, Aquatic bacteria, Bacteriophage, Biofilms, Disinfection, Fish, Gene probes, Groundwater pollution, Human diseases, Legionella, Parasites, Shellfish, Viruses, Wastewater, Water quality standards.

These proceedings present peer-review-selected papers on health aspects of microbiology. Epidemi-ological studies and research on the quality of water supplies have revealed that drinking water may constitute meaningful to extensive health risks may constitute meaningful to extensive health risks, but also in highly developed and industrialized countries. Population growth, which increases the demand for potable water and at the same time generates more wastes which may pollute available water resources, poses special challenges to all involved in the water industry. Progress in the development of practical and reliable methods for the assessment and control of the quality of water and wastes was a special feature of this symposium—a much better understanding has emerged of the present and future value of advanced gene probe and immunological techniques for the detection of viruses, bacteria, and protozoa. The 86 articles in this volume are grouped under the foltion of viruses, bacteria, and protozoa. The 86 articles in this volume are grouped under the following general headings: (1) Disease Outbreaks and Risk Assessment; (2) Microbiological Standards and Quality Control; (3) Bacteria in Drinking Water; (4) Bacteria in Fresh and Estuarine Waters; (5) Bacteria in Marine Waters; (6) Legionella and Biofilms; (7) Parasites; (8) Viruses in Water; (9) Virus Methods; (10) Bacteriophages; (11) Gene Probes; (12) Groundwaters and Bank Filtration; (13) Disiripaction; (14) Wastewaters; and (15) Eish (13) Disinfection; (14) Wastewaters; and (15) Fish and Shellfish. retrospective epidemiological study of cancer incidence was conducted in 3 communities along the River Elbe. Using the National Cancer Regis-ter, about 10,000 cases of different types of cancer suspected to be at least partially caused by polluted water were checked for the 17-year period 1968-1984. Study areas were those where the Elbe is the source of drinking water, while in control areas water is obtained from groundwater or reservoirs. water is obtained from groundwater or reservoirs. In Pirna, cancer of the stomach, colon, rectum, liver, pancreas, and kidney occurred more frequently in the study area. Differences are statistically significant for cancer of the stomach in both sexes, of liver in men, and of pancreas in women. In Dresden, a higher incidence was observed in the study area for center of stomach color rectum. study area for cancer of stomach, colon, rectum, gall bladder, pancreas, urinary bladder, and kidney. Statistical significance was evident for cancer of colon, rectum, and gall bladder in men and urinary bladder in both sexes. In Riesa, the incidence was higher in the study area for cancer of the rectum, liver, gall bladder, pancreas, urinary bladder, and kidney. Statistical significance could

### Water Treatment and Quality Alteration—Group 5F

be demonstrated for cancer of rectum and liver in men and for pancreas, urinary bladder, and kidney in women. The cancer risk related to the risk for all East Germany was as high as 145% for liver cancer in Piran (men), 160% for liver cancer and 170% for kidney cancer in Riesa, and 170% for kidney cancer in Riesa. It is concluded that a water-pollution-associated health risk cannot be rejected. (Author's abstract) W91-10614

NEED FOR NEW MICROBIOLOGICAL WATER QUALITY CRITERIA.
National Research Centre, Cairo (Egypt). Water n Control Lab. H. T. El-Zanfalv. Water Science and Technology WSTED4, Vol. 24, No. 2, p 43-48, 1991. 4 tab, 16 ref.

Descriptors: \*Bacteria, \*Drinking water, \*Egypt, \*Public health, \*Water quality standards, \*Water treatment, Antibiotics, Bacterial analysis, Cairo, Chlorination, Culturing techniques, Groundwater quality, Surface water.

The occurrence of antibiotic-resistant bacteria was assessed in treated drinking water and in untreated groundwater in Cairo. Resistant bacteria were found among standard plate count populations of found among standard plate count populations of chlorinated drinking water from two districts. Most strains appeared to be ampicillin-resistant (89%), followed by sulfaguanidine (78%) and streptomycin (57%). Most tested strains (62.4% to 98%) were multiple antibiotic resistant (MAR). Identification of MAR strains revealed that Gram-positive rods were dominant, followed by Gram-negative fermentative rods. Gram-positive conpositive rods were dominant, followed by Gram-negative fermentative rods, Gram-positive cocci, and Gram-negative nonfermentative rods. A total of 101 strains isolated from underground water pumped from three waterworks in Cairo were classified and tested for their resistance to four commonly used antibiotics and one chemotheracommonly used antiolous and one themotraction peutic agent (sulfanilamide pyrimidine). Results showed that 77, 64, and 32 isolates have resistance to penicillin, sulfanilamide pyrimidine, and tetracycline, respectively. Only 18 and 8 isolates were resistant to chloramphenicol and neomycin, re-spectively. It was also found that 19 isolates be-longing to 6 genera or groups were sensitive to-wards all of the tested compounds. It is concluded that data on MAR bacteria should be considered in water multir, deliberations and the regulation of water quality deliberations and the regulation of effluent quality. EVALUATION OF FECAL ENTEROCOCCI ISOLATION MEDIA TO INDICATE FECAL POLLUTION IN CHLORINATED WATER, Rand Water Board, Johannesburg (South Africa). C. M. E. de Wet, M. Grundlingh, B. Louw, and D.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 77-80, 1991. 1 tab, 11 ref.

Descriptors: \*Bioindicators, \*Chlorination, \*Culture media, \*Drinking water, \*Fecal bacteria, \*Water analysis, \*Water quality monitoring, \*Water tratment, Agars, Bacteria, Isolation, Performance evaluation, Water quality control.

The selectivity of mEnterococcus and KF strepto-The selectivity of menteroceus and Ar strepto-coccus agar or the isolation of fecal enterococci from chlorinated water were compared. Typical as well as atypical colonies were picked off and puri-fied for identification. Neither mEnterococcus nor streptococcus agar proved to be the ideal ation medium, as some 30% of the colonies isolation medium, as some 30% of the colonies with a typical appearance were catalase and benzidine positive, Gram-positive cocci. Catalase and benzidine negative, Gram-positive cocci isolated on KF streptococcus agar were identified as: Enterococcus faecalis (6%), E. faecium (7%), E. galliarum (2%), E. casselfiavus or E. mundtii (17%), E. avium (0.4%), E. durans (0.2%). Twenty-four percent could not be identified. Similar isolates on mEnterococcus agar were identified as: E. faecalis (14%), E. faecium (12%), E. galliarum (2%), E. percent could not be identified. Similar solates on mEnterococcus agar were identified as: E. faccalis (11%), E. faccium (12%), E. gallinarum (2%), E. casseliflavus or E. mundtii (36%), E. avium (1%) plus 9% that could not be identified. Results indiplus 9% that could not be identified. Results indicate that the use of either mEnterococcus or KF streptococcus agar for the indication of fecal pollution in chlorinated water has limited value. Isolates have to be identified to species level to confirm the presence of fecal enterococci. This practice is time-consuming and impractical for water quality control purposes. COLIFORM BACTERIA IN DRINKING WATER FROM SOUTH BAVARIA: IDENTIFICATION BY THE API 20E-SYSTEM AND RE-SISTANCE PATTERNS.

Landesuntersuchungsamt fuer das Gesundheitswe-sen Suedbayern, Munich (Germany, F.R.). P. R. G. Schindler, and H. Metz. Water Science and Technology WSTED4, Vol. 24, No. 2, p 81-84, 1991. 4 tab, 6 ref.

Descriptors: \*Analytical methods, \*Bacterial analysis, \*Coliforms, \*Drinking water, \*Germany, \*Water analysis, \*Water treatment, Bavaria, Citrobacter, Klebsiella, Seasonal variation, Serratia, Water quality standards.

A total of 256 coliform strains (132 from central, 124 from decentralized water supplies in Bavaria) as defined by the German drinking water regulation were characterized by the API 20E-system and by their susceptibility to 15 antimicrobial agents. Altogether, 22 different species from 10 genera could be differentiated, whereas 14 strains were unidentifiable by the system. The frequency distribution of the strains isolated from central water supplies yielded 48.5% for Citrobacter freundii, 17.4% for Klebsiella pneumoniae, 6.8% for Buttiauxella agrestis, and 6.1% for C. diversus. In decentralized water supplies. C. freundii was found in 33.9%, K. pneumoniae in 14.5%, Serration fonticola in 8.9%, and K. oxytoca in 6.5%. About one third (73 strains) were fully susceptible to all antibiotics tested. However, 42 strains displayed complete or moderate resistance against three or total of 256 coliform strains (132 from central, complete or moderate resistance against three or more agents. Within this group of multiresistant strains, a seasonal variation was evident. The pro-portion of multiresistant isolates was relatively

high in the first half of the year (21.4% from January to March and 29.4% from April to June) and relatively low in the second half of the year (7.9% from July to September and 11.3% from October to December). This distribution may indicate a conservation of R-factor-bearing bacteria in the environment. (See also W91-10612) (Author's abstract) W91-10627

EFFECT OF HEAT SHOCK ON RECOVERY OF ESCHERICHIA COLI FROM DRINKING WATER.

RObens Inst. of Industrial and Environmental Health and Safety, Guildford (England). C. Berry, B. J. Lloyd, and J. S. Colbourne. Water Science and Technology WSTED4, Vol. 24, No. 2, p 85-88, 1991. 1 fig, 11 ref.

Descriptors: \*Bacterial analysis, \*Culturing techniques, \*Drinking water, \*Escherichia coli, \*Temperature effects, \*Water analysis, \*Water treatment, Agars, Aquatic environment, Bacterial physiology, Culture media, Microscopy, Survival.

Recent studies have suggested that bacteria in the aquatic environment may enter a viable 'nonculturable phase' in response to stress. It has been found that mild heat shock causes viable nonculturable Legionella pneumophila to grow on laboratory media. The survival and culturability of Escherimedia. The survival and culturability of Escherichia coli in sterile drinking water was investigated using environmental, rather than clinical, isolates. As expected, the count by culture on nutrient agar declined with time while the microscopy count remained approximately constant. Under laboratory conditions, the E. coli isolates survived up to three months or more. After three months, a portion of each suspension was heat shocked at 35 C for 20 minutes and then assayed by culture and microscopy immediately. An average increase of three log cycles was noted in the count by culture. There was no corresponding increase in the count by microscopy. Thus, E. coli appears to exhibit viable nonculturable behavior; heat shock causes nonculturable bacteria to grow on artificial media. viable nonculturable behavior; heat shock causes nonculturable bacteria to grow on artificial media. Therefore, it cannot be assumed that bacteria like E. coli will necessarily die off in a low-nutrient environment, even after several weeks. It also cannot be assumed that simple culture techniques are adequate when assessing fecal pollution, and possible health risks, in such water. Mild heat treatment prior to culture might increase the likelihood of obtaining positive results. (See also W91-10612) (Doria-PTT)

BIODEGRADABLE DISSOLVED ORGANIC CARBON (BDOC) CONTENT OF DRINKING WATER AND POTENTIAL REGROWTH OF BACTERIA.

Centre de Recherche de Maisons-Laffitte (France). Centre de Nesterierie de Wassolis-Lainte (Plante). J. C. Joret, Y. Levi, and C. Volk. Water Science and Technology WSTED4, Vol. 24, No. 2, p 95-101, 1991. 3 fig, 1 tab, 13 ref.

Descriptors: \*Bacterial growth, \*Bioassay, \*Biodegradation, \*Dissolved organic carbon, \*Drinking water, \*Organic carbon, \*Water analysis, \*Water treatment, Aeration, Bacteria, Chlorination, Disinfection, Incubation, Nutrients, Organic com-pounds, Sand, Wastewater facilities, Water distri-bution.

Total organic carbon (TOC) is not a good predictor of bacterial regrowth in distribution systems because the ratio of organic nutrients to TOC is not constant. Therefore, methods are needed for rapidly estimating the quantities of organic nutri-ents in finished water samples. Attempts have been made to assess the total amount of biodegradable made to assess the total amount of biodegradable organic carbon (BDOC) in drinking water. In this investigation, BDOC in water was evaluated by the reduction of dissolved organic carbon (DOC) during an ultimate biodegradation process in the presence of natural and fixed bacteria in aerated conditions. The inoculum consisted of 100 g of prewashed biological active sand (BAS) from a wastewater treatment plant without any prechlorination. BAS was prewashed with distilled water

### Group 5F—Water Treatment and Quality Alteration

until no detectable DOC is released, then added to 300 ml of the water sample. Using such an abundant fixed flora allows both a rapid response (3-5 days) and no organic contamination of the sample. DOC values were recorded daily until a minimum was reached. The BDOC of the water sample was advanted by their or the different particular or the sample was reached. The BDOC of the water sample was reached that the sample was a secondated to the sample was a seconda was reached. The BJDC of the water sample was calculated by taking the difference between initial and minimum DOC reached after a few days' incubation period of the aerated sample incubated at 20 C in contact with BAS. The bioassay was found to be accurate, precise, reproducible, and sufficiently sensitive even for distributed water. (See also W91-10612) (Doria-PTT)

ELIMINATION OF COLIPHAGES, CLOSTRID-IUM PERFRINGENS AND HUMAN ENTERIC VIRUSES DURING DRINKING WATER TREATMENT: RESULTS OF LARGE VOLUME SAMPLINGS.

Institut Armand-Frappier, Laval (Quebec).

P. Payment.

Water Science and Technology WSTED4, Vol. 24, No. 2, p 213-215, 1991. 2 tab, 4 ref.

Descriptors: \*Bacteriophage, \*Bioindicators, \*Clostridium, \*Viruses, \*Water treatment, Agars, Assay, Chlorination, Escherichia coli, Filters, Filtration, Immunoassay, Membrane processes, Ozonation, Pollutant identification, Sample preparation, Sampling, Water analysis.

The elimination of human enteric viruses, coliphages, and Clostridium perfringens by drinking water treatment was studied using a single filtration method of 100 L (raw and settled water) or 1,000 L (filtered tap water). The VIRADEL method was used to concentrate these organisms method was used to concentrate these organisms on electronegative filters. Concentrates were assayed for human enteric viruses on MA-104 cells using two blind passages and an HISG-immunoperoxidase method. Coliphages were assayed by plaque assay using a nalidixic acid resistant ATCC 13706 E. coli host strain by the double layer agar method. Clostridium perfringens were enumerated by membrane filtration on m-CP agar. The water filtration plant studied uses full conventional treatment, including ozonation and postchlorination. Results suggest that, using similar volumes of waters for the detection of these indicators, colihages and C. perfringens are slightly more resistphages and C. perfringens are slightly more resist-ant than cultivable human enteric viruses and that they could therefore serve as rapid indicators for the elimination of human enteric viruses in treated waters. Large volume samplings are necessary to evaluate the virological quality drinking water correctly even when using potential indicators such as coliphages and clostridia. The methods used in this coliphages and clostridia. The methods used in this study still rely on sampling large volumes of water, although results were obtained much more rapidly: 6-25 h for coliphages and 48 h for clostridia, compared to several days or weeks for most virological analyses. EFFECTIVITY OF CHLORINE DIOXIDE TO CONTROL AEROMONAS IN DRINKING WATER DISTRIBUTION SYSTEMS. Rijksinstitut voor de Volksgezondheid, Bilthoven (Netherlands). Lab. for Water and Food Microbi-

G. J. Medema, E. Wondergem, A. M. van Dijk-Looyaard, and A. H. Havelaar. Water Science and Technology WSTED4, Vol. 24, No. 2, p 325-326, 1991.

Descriptors: \*Aeromonas, \*Bacteria, \*Chlorina-tion, \*Chlorine dioxide, \*Disinfection, \*Drinking water, \*Water treatment, Dissolved organic carbon, Mortality, Residual chlorine, Water con-

Chlorine dioxide was evaluated as a disinfecting agent to control Aeromonas in drinking water distribution systems. It was found that the ClO2 demand of drinking water is primarily a function of the dissolved organic carbon (DOC) content and the initial ClO2 concentration. In most drinking waters, a ClO2 dose of 0.2 mg/L is completely consumed within 10 min. Aeromonas is relatively sensitive to ClO2 compared to other Gram-negative bacteria. There is no significant difference in the sensitivity to ClO2 between laboratory cultures and natural populations of Aeromonas. Therefore, the results of the model experiments can be extrapolated directly to disinfection practice. Aeromonas is as sensitive to ClO2 as to free available chlorine at nH 80. Chloring dioxide can be an effective. at pH 8.0. Chlorine dioxide can be an effective agent for post-disinfection provided the ClO2 demand of the receiving water is low. Significant die-off of Aeromonas occurs only in the presence of a residual ClO2 concentration; reaction products of a residual LO2 concentration; reaction products such as chlorite or chlorate have no effect on growth of Aeromonas in the range of the concentrations present in drinking water (1 mg/L). The use of ClO2 for protection against growth of Aeromonas in distribution networks at a dose of 0.2 mg/ monas in distribution networks at a dose of 0.2 mg/L is limited to waters that are treated with activated carbon and/or have a low DOC content. For effective protection, a ClO2 residual should be maintained throughout the network. In most water types, this can be established only be addition of higher ClO2 doses (0.5-1 mg/L). The presence of high numbers of Aeromonas spp. is undesirable in the water supply, as they are potentially pathogenic and may cause food spoilage. Aeromonas spp. have been found in chlorinated drinking water where coliform counts were low. A study was conducted to examine the level of and variation in chlorine resistance of Aeromonas present the supplementation of monas spp. Two methods were employed. Screening of relative chlorine resistance was done on 46 clinical and 41 environmental isolates of Aeroclinical and 41 environmental isolates of Aeromonas spp. at 30 C using a disk assay with four concentrations of hypochlorite, and results were compared with those for Escherichia coli, Pseudomonas fluorescens, Klebsiella, P. aeruginosa, and Acinetobacter. Resistance varied greatly between Aeromonas isolates, but they were in general more susceptible than the other bacteria tested. Inactivation studies were conducted following the survival of selected isolates in solutions of manchloramine of selected isolates in solutions of monochloramine (0, 0.5, 1.0, and 2.0 mg/L) over a period of 180 minutes at pH 7.0 and 10 C. The most resistant strain in the disk assay was also the most resistant strain in the disk assay was also the most resistant in the inactivation study. No significant variation was observed with relation to Aeromonas species, or with relation to the origin of the isolates. However, it should be noted that only a few of the isolates came from chlorine-stressed environments with selective pressures. (See also W91-10612) (Author's abstract) W91-10678

COMPARATIVE INACTIVATION OF HEPATITIS A VIRUS AND OTHER ENTEROVIRUSES IN WATER BY IODINE.

NWATER BY RODINE.
North Carolina Univ., Chapel Hill. Dept. of Environmental Sciences and Engineering.
M. D. Sobsey, C. E. Oldham, and D. E. McCall.
Water Science and Technology WSTED4, Vol.

\*Disinfection. Descriptors: \*Enteroviruses. Hodine, \*Viruses, \*Water treatment, Bentonite, Buffering, Fulvic acids, Humic acids, Hydrogen ion concentration, Phosphates, Temperature, Turbidity.

Iodine is used as a disinfectant of small and field water supplies, but little is known of its ability to inactivate important waterborne viruses such as hepatitis A virus (HAV). The inactivation of purified, aggregated HAV, poliovirus type 1, and echovirus types 1 and 8 were determined in the laboratory using 1, 8, and 16 mg/L doses of iodine in both phosphate buffered, iodine-demand-free (clean) water and the same water containing 10 mg/L of a 1:1 mixture of humic and fulvic acids and 5 NTU of bentonite clay turbidity (dirty and 5 NTU of bentonite clay turbidity (dirty water). Virus inactivation studies in clean water were done at pH 4.5, 7.0, and 9.5 and at 5 and 25 C, and in dirty water at the same pH levels but at 5 C only. Iodine in doses of 8 and 16 mg/L in clean water produced 99.99% or 4 log(base 10) inactivation of HAV by 60 min or less. Four log(10) inactivation of polio 1 and echo 1 was not achieved in 60 min by 8 mg/L iodine at 5 C and pH 7.0 and inactivation of polio 1 and echo 1 was not achieved in 60 min by 8 mg/L loidine at 5 C and pH 7.0 and 4.5 or by 16 mg/L loidine at 5 C and pH 4.5. HAV was inactivated more efficiently by iodine than were the other two test viruses, and the overall order of virus inactivation was: HAV > echo 1 > polio 1. Virus inactivation was generally more effective at higher pH, in cleaner water, at higher temperature, and at higher iodine dose. (See also W91-10612) (Author's abstract) W91-10679

UV DISINFECTION: SHORT TERM INACTI-VATION AND REVIVAL.

Descriptors: \*Bacterial growth, \*Disinfection, \*Ultraviolet radiation, \*Water treatment, Bacteria, Escherichia coli, Groundwater, Microbiological studies, Organic matter, Surface water, Wastewater.

The regrowth potential of bacteria sublethally injured by ultraviolet (UV) treatment was investigated using a laboratory culture of Escherichia coil and natural mixed populations isolated from wastewater and stream water. Regrowth subsequent to 4 min UV radiation of E. coli suspensions ccurred under both light and dark storage conditions. Similar responses were noted with a natural stream sample and with a suspension of 1% wastewater in groundwater. Following continuous UV treatment, there appeared to be a direct relationship between the intensity of radiation and the tionship between the intensity of radiation and the potential for regrowth and repair. Moreover, the more intense the level of irradiation, the greater the extent of lysis of refractory substrates and of susceptible bacteria, resulting in the release of organic material available for reassimilation by bacteria able to regrow in the system. Continuous irra-diation of the mixed bacterial culture in river water diation of the mixed bacterial culture in river water resulted in 100% suppression of the bacteria after 1 hour. However, continued irradiation resulted in the appearance of UV-resistant bacteria in the supension, which were apparently able to grow on the lysis products of other bacteria from the suspension. Therefore, after 3 days the total cell counts were comparable to those found following 4 min of irradiation. It is concluded that regrowth is enhanced by increasing UV intensity in waters containing residual organic matter, and that the treatment of such waters using UV irradiation should be reevaluated. ### Water Treatment and Quality Alteration—Group 5F

Prevention of disease transmission in swimming and bathing pools requires maintenance of adequate disinfection capability in the water. Therefore, German regulations require that any procedure for the treatment and disinfection of such water must guarantee a minimum degree of inactivation of human pathogens. A simple method was developed for evaluating the disinfection capability of pool water, expressed as the inactivation rate of selected microorganisms (Pseudomonas aeruginosa, Escherichia coli, and Legionella pneumophila). The test can be carried out onsite in the pool area using simple, standard equipment normally present in microbiological laboratories, and may be used for the evaluation of standard disinfectants as well as those developed in the future. Results achieved with this test show good agreement with those obtained using a sophisticated stopped-flow apparatus developed exclusively for the evaluation of disinfection capability. It is proposed that the reduction of the concentration of P. aeruginosa (starting with a concentration of approximately 1 million cfu/ml) within 30 seconds is to be called 'disinfection capability,' equivalent to the concentration of the indicator bacteria expressed as its decadic logarithm at time zero minus the concentration of the bacteria expressed as its decadic logarithm at time zero minus the concentration of the bacteria expressed as its decadic logarithm at time zero minus the concentration of the bacteria expressed as its decadic logarithm at time 20. Only those pool water treatments with a disinfection capability under maximal operating conditions (high density of users) of 4 or higher are considered to have achieved a safe hygienic condition. Descriptors: \*Air flotation, \*Algae, \*Dissolved air flotation, \*Humic substances, \*Water treatment, Alum, Flocculation, Halides, Polyaluminum chloride, Turbidity.

Dissolved air flotation (DAF) is used in place of conventional gravity settling as a means to separate low density floc particles from water. A comparison was made between DAF and conventional water treatment of coagulation-flocculation followed by gravity settling (CGS) for removals of particles, color, dissolved organic carbon (DOC), trihalomethane (THM) precursors, and total organic halide (TOX) precursors. In addition, the effects of raw water quality, water temperature, chemical variables, flocculation period prior to DAF, and DAF design and operating variables on DAF performance were examined along with an evaluation of alum and polyaluminum chloride (PACI) as pretreatment coagulants for DAF. Results of the DAF experiments, using both synthetic and natural waters, showed that good DAF treatment requires good coagulation; flotation without a prior flocculation period is effective. For waters containing humic substances, there was no significant difference in the removal of UV, true color, dissolved organic carbon, and dissolved organic halide precursors (THM and TOX) between DAF and conventional treatment. However, DAF produced significantly lower turbidities than conventional treatment for all raw water systems, particularly at colder water temperatures. For waters containing algae, DAF produced much greater reductions in algal cell concentrations than conventional treatment. (Author's abstract)

The feasibility of using polyclonal antibodies raised against a bovine serum albumin (BSA)-argosmin C conjugate to develop an enzyme-linked immunosorbent assay (ELISA) for geosmin was investigated. A direct competitive ELISA for geosmin (a musty/earthy off-flavor compound found in drinking water produced as a metabolite by blue-green algae) was developed. Antibodies were produced in goats injected with a BSA-argosmin C (a dehydration product of geosmin) conjugate. The sensitivity and specificity of the antibody were respectively determined in a microtiter plate coated with the purified antibody which was subsequently detected with an alkaline phosphatase-argosmin C conjugate. The antibody had the most cross-reactivity with an argosmin C related compound, namely, 4,4a,5,6,7,8-hexahydro-4s-methyl-2(3H)-naphthalenone. It cross-reacted equally with geosmin, 2-ketogeosmin, and 2-decalone but had limited recognition for norbornane, indicating that the bidding of the antibody was restricted mainly to the bicyclic structure (A and B rings) of geosmin. Because it had some cross-reactivity with 2-methylisoborneo(MIB), it was assumed that the methyl group in geosmin might also play a role in antibody recognition. In addition, the presence of two OH groups on the A and B rings of 1,5-decalindiol also had an effect on the antibody binding. The assay had a sensitivity of 1 microgram/mL. (Author's abstract)

ANALYSIS OF HALOGENATED ACETIC ACIDS IN DUTCH DRINKING WATER. Rijksinstituut voor de Volksgezondheid en Milieuhygiene, Bilthoven (Netherlands). R. J. B. Peters, C. Erkelens, E. W. B. de Leer, and L. de Galen. Water Research WATRAG, Vol. 25, No. 4, p 473-477, April 1991. 3 fig, 2 tab, 14 ref.

Descriptors: \*Acetic acid, \*Acids, \*Drinking water, \*Halogenated organic compounds, \*The Netherlands, \*Water analysis, Analytical methods, Chlorination, Disinfection, Groundwater, Surface water, Water quality control.

Halo-acetic acids are produced during chlorine disinfection of drinking water. Besides the well known dichloro-, and trichloroacetic acid, brominated and mixed chloro/bromo acetic acids are also produced. A method was developed to determine all halo-acetic acids. This method was applied for the analysis of 20 drinking waters prepared from different source waters. Halo-acetic acids were found in all drinking waters prepared from surface water while they could not be detected in drinking waters prepared from groundwater. The acid concentrations were in the range of 0-14.7 microgram/L and dibromoacetic acid was found to be the most prominent halo-acetic acid in chlorinated waters. Brominated acetic acids accounted for 65% of the total acid concentration showing that brominated compounds form a large part of the chlorination roducts. The total halo-acetic acid concentration correlated positively with the chlorine-to-carbon ratio and with the adsorbable organic halogen, to which it accounted for 15%. (Author's abstract) W91-10938

ALGICIDAL AND CHEMICAL EFFECT OF U.V.-RADIATION OF WATER CONTAINING HUMIC SUBSTANCES,

Norsk Inst. for Vannforskning, Oslo. E. T. Gjessing, and T. Kallqvist. Water Research WATRAG, Vol. 25, No. 4, p 491-494, April 1991. 2 fig, 1 tab, 4 ref.

Descriptors: \*Algicides, \*Chemical properties, \*Disinfection, \*Humic substances, \*Ultraviolet radiation, \*Water treatment, Acidic water, Algal growth, Drinking water, Microorganisms, Organic matter, Ozone.

Ultraviolet (UV) radiation is increasingly used to disinfect drinking water. In addition to an effect on microorganisms, both artificial and natural UV-radiation transforms chemicals in water. The effect of UV on humie substances (HS) in water acquires increasing relevance because of the anticipated increase in global radiation, as a consequence of the reduced ozone content in the stratosphere. Experiments were conducted using typical surface water with humic substances. The results show that UV-radiation of humus water changes the chemical composition of water, including acidity and charge density and also inhibits the growth of the alga Selenastrum capricornutum. Inhibition increases with increased 'UV-dose' from a mercury lamp. The algicidal effect apparently lasts for several weeks. The observed action of UV-treated humus water may be explained by photon-initiated interactions of HS and other chemicals in the water which results in the formation of oxidizing reagents such as OH radicals; these in turn oxidize organic materials by hydrogen abstraction. ANALYSIS OF LARGE SCALE WATER DISTRIBUTION SYSTEMS.

Akron Univ., OH. Dept. of Civil Engineering. S. Sarikelle, and Y. Chuang. Journal of Hydraulic Research JHYRAF, Vol. 29, No. 1, p 5-13, 1991. 2 fig, 4 tab, 13 ref.

Descriptors: \*Flow models, \*Hydraulic design, \*Hydraulic engineering, \*Model studies, \*Water conveyance, \*Water distribution, Computer models, Computer programs, Computing time, Conveyance structures, Pipes, Simulation analysis.

A variety of methodologies is currently available for computing flows in water distribution systems. One the these methods is the Newton-Raphson Method which regenerates and factorizes Jacobian matrix at each iteration. In this method a great deal of computational effort is consumed in the determination and factorization of the Jacobian matrix. One alternative approach is to use the initial Jacobian matrix throughout, thus avoiding the expense of reforming and triangularizing the Jacobian matrix. However, in this approach, the quadratic convergence characteristic of the Standard Newton-Raphson Method is no longer maintained. As a compromise between these two approaches, a

### Group 5F—Water Treatment and Quality Alteration

class of methods known as Quasi-Newton Methods can be utilized. A computer model has been devel-oped which incorporates the use of Quasi-Newton Methods in the solution of large scale water distribution systems. Three water distribution systems of varying sizes were analyzed using this method. The computer results obtained using the Quasi-Newton Raphson Method were compared to those obtained by the Standard Newton Raphson Method. The results show that the Quasi-Newton Method allows substantial saving of central processing unit (CPU) time, particularly if continuous simulation studies (time extended) of the distribution systems are undertaken, and is efficient in handling large scale water distribution systems. REMOVAL OF BIOTA FROM INTER-BASIN TRANSFER WATER. North Dakota Univ., Grand Forks. Dept. of Civil

Engineering.
C. D. Turner, and M. Hefta.
IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 129-138, 4 fig,

Descriptors: \*Biological studies, \*Ecological effects, \*Hudson Bay Watershed, \*Interbasin transfers, \*Missouri River Basin, \*Water quality control, \*Water resources development, \*Water treatment, Case studies, Filtration, Garrison Diversion Project, North Dakota, Pathogens, Turbidity, Water treaffer.

The potential transfer of biota from the Missouri River Basin into the Hudson Bay Basin has become the central argument for not diverting water via the Garrison Diversion Project in North Dakota into either the Sheyenne River drainage or the Devils Lake Basin. Both the Sheyenne River and Devils Lake drain into the Red River of the North which enters Canada via Manitoba and eventually empties into the Hudson Bay. Earlier efforts to design an effective barrier to biota transfer were reviewed along with an examination of current research efforts to design a cost-effective system for biota removal. Early efforts involved the design and testing of fish screens by the US Bureau of Reclamation. Current efforts center around direct filtration, a potable water treatment method suitable for treating raw water with low turbidity. suitable for treating raw water with low turbidity.

A direct filtration process development unit (PDU) was operated in the laboratory using synthetic Garrison water and subsequently moved to Garrison for on-site testing. Test results indicate that direct filtration is suitable for use with Garrison. raw water and that the fish pathogen, Yersinia ruckeri, can be effectively destroyed using post-disinfection. HOME WATER TREATMENT: REMEDIATING ALDICARB CONTAMINATION IN SUFFOLK COUNTY, NEW YORK. Suffolk County Dept. of Health Services, Haup-

pauge, NY. D. Moran.

IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 291-299, 2 tab.

Descriptors: \*Aldicarb, \*Granular activated carbon, \*New York, \*Nonpoint pollution sources, \*Pesticides, \*Water quality control, \*Water treatment, \*Well water, Drinking water, Groundwater pollution, Pesticide residues.

Pesticide contamination was first discovered in Suffolk County in August 1979 when the carba-mate pesticide aldicarb (Temik) was detected in drinking water supply wells. As a result of this finding, an extensive testing program for aldicarb and other carbamate pesticides was initiated. The testing program revealed that extensive contamination of groundwater resources had occurred in the agricultural areas of eastern Suffolk County. Reediation involved the use of granular activated

carbon (GAC) treatment units in homes with wells containing aldicarb residues above 7 ppb. Based upon eight years of experience it has been found that the home treatment program is a viable option to address the aldicarb contamination problem. It must be realized that implementation of such a program involves significant operation, mainte-nance, and administrative efforts. Responsible ac-tions on the part of the pesticide manufacturers in providing support have contributed to the success of the program. (See also W91-11162) (Korn-PTT) W91-11189

WATER AND HUMAN HEALTH.
Johns Hopkins Univ., Baltimore, MD. School of Engineering. A. Wolman.

A. Wolman.

IN: A 25th Anniversary Collection of Essays by Eminent Members of the American Water Resources Association. AWRA Special Publication No. 89-2. American Water Resources Association, Bethesda, Maryland. 1989. p 31-40. 6 ref.

Descriptors: \*Developing countries, \*Drinking water, \*Human diseases, \*Public health, \*Sanitation, \*Water quality control, Africa, Economic aspects, Social aspects, Water conservation, Water pollution, Water resources management.

The objectives of the International Water and Sanitation Decade, 1980-1990, are lofty-safe drinking water for all. Predictably, water has been delivered and excreta have been removed for large numbers of people hitherto unserved. Coverage, however, has not been universal. Preparation for implementation of projects has taken longer than was hoped. The americas have the oldest orga-nized approach to the issues. Africa, on the other hand, has emerged only within the last half a century with deliberate public health programs. Of the may constraints to safe drinking water, four are outstanding: lack of motivation, inadequate personnel, poor management, and shortage of money. Greater emphasis should be placed on using local money, local institutional structures, and most importantly, local people. Education and leadership may most effectively come from an underused source--local women. Diseases that affect humans appear in three categories: (1) diseases carried by water; (2) water-based diseases, whose infecting agents develop in aquatic animals; and (3) diseases agents develop in aquatic animals; and (3) diseases related to poor sanitation and insufficient water for proper hygiene. Successes in the prevention and virtual elimination of communicable diseases were great in the western world. The picture in developing countries remains dismal. By the year 2000, conservation of water resources will have to include reuse of treated sewage and the application of a closed cycle of water use in municipalities and industries. Manmade and natural chemicals are the most recent threat to the water supply. The chalmost recent threat to the water supply. The challenge ahead in the water management field is par-ticularly difficult, because the manifestation of in-sults to water has been going on for decades. (See also W91-11206) (Mertz-PTT) W91-11211

PACKAGE WATER PLANT FILTERS TO 0.02

June Lake Public Utility District, CA.

Water Engineering and Management WENMD2, Vol. 138, No. 4, p 28-29, April 1991. 1 ref.

Descriptors: \*Filters, \*Giardia, \*Viruses, \*Water treatment, California, Cost analysis, Filtration, Flocculation, June Lake, Performance evaluation, Turbidity, Water quality management.

Removing Giardia cysts and viruses from cold, clear, pristine waters can be difficult. At June Lake, California, waters of turbidity < 0.2 nephelometric turbidity units (NTU), 32-45 F, and total dissolved solids < 100 mg/L, little or no color,

and no appreciable iron-manganese are used for water supply. A treatment plant at a remote loca-tion was designed that specified dual process trains rate for 120 gpm each (manufactured by Culligan). The process trains include two 6 ft-diameter floc-culator vessels followed by their respective 7 ft-diameter filter vessels. The flocculation vessels are diameter litter vessels. In the footcomment vessels are popy-lined tanks full of coarse monomedia (= contact floculators or clarifiers). Coagulant mixing occurs within the clarifiers. The floculator units remove most of the raw water particulate units remove most of the raw water particulate load and they simultaneously condition water for filtration. Typically the effluent turbidity of the process falls well under 0.1 NTU, at times as low as 0.02 NTU, even with raw water values above 5 NTU for short periods. Filter backwash, concurrent with flocculator backwash, usually is required only bi-weekly or even less frequently based on head loss. The unit and appurtenances was delivered for \$100,000, which works out to \$300/gpm of true) process canactive exclusive of housing. of (true) process capacity, exclusive of housing, piping the units to the exterior piping system and process monitoring instrumentation (i.e., turbidimeters). FLOCCULATION OF MICRO-ORGANISMS. Wahnbachtalsperrenverband, Siegburg (Germany, F.R.).

H. Bernhardt, and J. Clasen. Aqua AQUAAA, Vol. 40, No. 2, p 76-87, April 1991. 17 fig, 43 ref.

Descriptors: \*Flocculation, \*Particulate matter, \*Water treatment, Aluminum salts, Electrical charge, Electrochemistry, Iron salts, Microorganisms, Plankton, Polymers

The removal of microorganisms by flocculation and filtration is one of the major problems in treating reservoir water, especially if the water shows a very high plankton production due to eutrophication. Flocculation of algae and bacteria conforms in principle to an adsorption coagulation with charge neutralization, provided that the cells of both bacteria and algae are smooth and more or less spherical. There is a stoichiometric relationship between the total surface area of the particle ship between the total surface area of the particle (surface concentration), i.e., the cell concentration, and the chemical dosage required for the floccula-tion process. The effects of differently charged organic polyelectrolytes and polymers on the floc-culation process were examined and their influence was compared with that of inorganic iron and aluminum salts, which form differently charged polyhydroxo complexes during hydrolysis depend-ing on the flocculation pH value. The elimination

### Water Treatment and Quality Alteration—Group 5F

of planktonic cells depends strongly on the type of plankton present and varies from 50 to 99.9%. The required flocculant dose of cationic polyelectrolytes or positively charged metal hydroxo complexes is markedly determined by the amount of negative charge density of the algae and their growth phase. Filamentous algae, large algae, or species with bristles on their cell surface do not too from to the stoichingteric rules. A satisfactory species with bristles on their cell surface do not conform to the stoichiometric rules. A satisfactory flocculation of these algae will be possible only if large amounts of aluminum hydroxide flocs are produced in the water that then enclose the algal cells (sweep coagulation). Planktonic motile organisms are a problem in flocculation and filtration because they can break away easily from produced flocs. The inactivation of their motility is indispensible if flocculation and floc separation is to be flocs. The mactivation of their motility is indispen-sable if flocculation and floc separation is to be improved. Methods to accomplish this inactivation include use of oxidizing agents such as ozone, potassium permanganate, chlorine, or chlorine di-oxide. (Rochester-PTT) W91-11267

EFFICIENCY OF AN OZOFLOTATION-FIL-TRATION PROCESS FOR THE TREATMENT OF THE RIVER THAMES AT WALTON WORKS.

WORKS.
Anjou Recherche, Maisons-Laffitte (France). Lab. d'Hygiene et Recherche en Sante Publique.
M. M. Bourbigot, N. Martin, M. Faivre, K. Le Corre, and S. Quennell.
Aqua AQUAAA. Vol. 40, No. 2, p 88-96, April 1991. 8 fig, 9 tab, 5 ref.

Descriptors: \*Filtration, \*Ozoflotation, \*Ozona-tion, \*Water treatment, Algae, Chlorophyll, Disin-fection, England, Organic matter, Ozone, Perform-ance evaluation, Sand filters, Thames River, Tur-bidity, Walton Works.

The current treatment of Thames River water (England) at Walton Works is conventional. After tengiand) at waiton Works is conventional. After settlement, with or without pretreatment, the water flows to the primary rapid filters. The primary filtrate then flows to secondary slow-sand filters. The secondary filtrate is passed to a contact tank for disinfection. To improve the current water treatment (high algal content currently causes taste and odor problems and close filtrate), the combiner treatment (high algal content currently causes taste and odor problems and clogs filters), the combination of ozoflotation with filtration was tested in a pilot plant. The ozoflotation process is a combination of pre-ozonation treatment and conventional flotation. It associates the physical aspects of flotation with the oxidation effects of ozone. The pilot plant included the ozoflotation unit with two combinations with the ozoflotation unit with two combinations are proposed to the open or problems. partments and two filters that work in parallel. A total of 7.5 min contact was used in the two compartments of the ozoflotation contactor. After compartments of the ozoflotation contactor. After ozoflotation, water was passed either through a granulated-activated carbon (GAC)-sand filter or a plain sand filter. Based on the results of several tests carried out with this pilot plant, the following conclusions were drawn: (1) water quality is better with ozoflotation and filtration than with direct filtration; (2) the GAC-sand filter showed better performance than the sand filter (with regard to color, UV 254 mm an 270 mm, turbidity, organic matter, chlorophyll, algae, and head loss); (3) algal elimination due to ozoflotation equals or exceeds algal elimination at the outlet of direct sand filtration; (4) ferric chloride used as a flocculating agent allows better water quality and a better filter peruon; (9) rerrie enioride used as a flocculating agent allows better water quality and a better filter per-formance than polyaluminum chloride; and (5) sweeping of the porous plates is essential to obtain good water quality and satisfactory filter perform-ance. CRITERIA FOR FLOCCULATOR DESIGN. Hokkaido Univ., Sapporo (Japan). Dept. of Envi-ronmental and Sanitary Engineering. N Tambo

Aqua AQUAAA, Vol. 40, No. 2, p 97-102, April 1991. 6 fig, 15 ref.

Descriptors: \*Design criteria, \*Flocculation, \*Water treatment, \*Water treatment facilities, Energy, Mathematical equations, Performance tion, Sanitary engineering.

In 1953, the practical use of the mean velocity gradient G-value and non-dimensional GT-value

theory for flocculator design to make better flocs theory for flocculator design to make better flocs was proposed. Subsequently, it was proposed that non-dimensional product GC sub 0T determines the progress of flocculation rather than GT value. (G is the mean velocity gradient of the agitation field (I/s), C sub 0 is the initial volume concentration of flocs (non-dimensional), and T is the elapsed time for flocculation.) The value of G etapsed time for inoccutation.) The value of G = the square root of epsilon/mu, in which epsilon is the total mean dissipation of energy (watts/cu m) and mu is the absolute viscosity (Pa . second). Flocculation kinetics are summarized here and a set of practical design criteria is proposed, that is, G and the GC sub 0T values. The use of GC sub of an the GC sub of values. The use of GC sub off = 1.0 is proposed as the criterion to reach an ultimate floc growth rate in a conventional flocu-lator followed by sedimentation. For another kind of floculator design applied for a direct filtration that needs only a small increase in floc size, a much higher GC sub off value, such as 5, is recommended. USE OF A BACKFLUSH TECHNIQUE IN CROSS-FLOW MICROFILITRATION FOR TREATING NATURAL WATER AND FILTER BACKWASH WASTEWATER IN WATER

Asian Inst. of Tech., Bangkok (Thailand). Div. of Asian inst. of rech., Bangkok (Thanand). Div. of Environmental Engineering. S. Boothanon, H. Prasanthi Dharmappa, S. Vigneswaran, and R. Ben Aim. Aqua AQUAAA, Vol. 40, No. 2, p 103-109, April 1991. 5 fig, 3 tab, 3 ref.

Descriptors: \*Backflushing, \*Filtration, \*Potable water, \*Wastewater treatment, \*Water treatment, Backwash wastewater, Cross-flow microfiltration, Water treatment facilities.

Cross-flow microfiltration (CFMF) is useful in Cross-flow micronitration (CFMF) is useful in treating natural water for potable purposes, be-cause it is very efficient in completely removing all particles within the size range 0.01 to 10 microme-ter, including bacteria. It also can be used to treat the filter backwash wastewater produced in a water treatment plant. Although CFMF is a very water treatment plant. Although CFMF is a very effective technique for treating natural water and filter backwash wastewater, problems such as fouling, deposition, and internal clogging affect the efficiency of the process. The backflush technique in CFMF is one of the most useful techniques for minimizing these problems. Laboratory-scale CFMF experiments were conducted using the backflush in treating natural water and filter backwash wastewater to study the effect of operating parameters, such as backflush frequency and backflush duration, on CFMF performance. For natural water treatment, the permeate flux increased by water treatment, the permeate flux increased by 24% when the backflush technique was used and 24% when the backflush technique was used and for backwash wastewater treatment it increased by 400%. The low turbidity (0.1-0.3 NTU) of the permeate proves the applicability of CFMF to potable water treatment. When filter backwash wastewater was used as feed, the optimum backflush frequency and backflush duration for obtaining maximum flux were 1 min and 2 sec, respectively. The flux of 1.175 cu m/sq m per hachieved here is a breakthrough in membrane process technology (Author's sharter) cess technology. (Author's abstract)

CRYPTOSPORIDIOSIS AND WATER SUPPLY: A BRIEF REVIEW, WITH SPECIAL REFERENCE TO THE REPORT OF THE BADENOCH COMMITTEE. North Surrey Water Co., Staines (England).

J. Jeffery. Aqua AQUAAA, Vol. 40, No. 2, p 110-115, April 1991. 15 ref.

Descriptors: \*Cryptosporidium, \*Drinking water, \*England, \*Human diseases, \*Water treatment, Badenoch Committee, Chlorine dioxide, Epidemics, History, Ozone, Public health.

Awareness of the pathogenic significance of Cryptosporidium and of the possibility of waterborne infections has increased rapidly during the 1980s. Following an outbreak of cryptosporidiosis in Swindon (England) and parts of Oxfordshire early

in 1989, the British Government set up a group of experts under the chairmanship of Sir John Badenoch to advise on Cryptosporidium and water supplies. Information on Cryptosporidium, including the organism's characteristics, recorded outbreaks of Cryptosporidium, and the implications of this or Cryptosportalum, and the implications of this organism in water treatment is reviewed based on material from the Badenoch committee report. Consequences of events in 1989-1990 that affected the North Surrey Water Company also are described. Nine thousand cases of cryptosportidoss were reported in Britain in 1989. Water treatment processes generally were not designed to deal with occysts, which generally are unaffected by doses of chlorine considerably higher than those used in water treatment. A safe and effective disinfectant is needed; preliminary results suggest that ozone or chlorine dioxide may suffice, but more work is needed. Until an effective disinfectant is found, the needed. Only an effective dismerciant is found, the passage of occysts into the water supply will be prevented by catchment control and by skilled operation at maximum efficiency of existing treat-ment systems. SITUATION OF WATER SUPPLY IN THE NEW LANDER OF THE FEDERAL REPUBLIC OF GERMANY.

I. W. Merkel. Aqua AQUAAA, Vol. 40, No. 2, p 116-119, April 1991. 1 fig, 1 tab.

Descriptors: \*Drinking water, \*Germany, \*Governmental interrelations, \*Public health, \*Wastewater pollution, \*Water treatment, Facilities management, Management planning, Nitrates, Public policy, Wastewater treatment facilities, Water quality standards, Water use.

Since November 1989, when the Berlin Wall was Since November 1989, when the Berlin Wall was destroyed, steady progress was made toward German unification. Now that unification has taken place, the task remains of bringing public services in the former East Germany up to the levels attained in West Germany. The former German Democratic Republic had a surface area of 108,000 sq km, 16.5 million people, and a water use (not including power production) of 8.2% of the runoff. Comparable figures for the Federal Republic of Germany arise to unification were the runoff. Comparable figures for the Federal Republic of Germany prior to unification were: 249,000 sq km, 62.5 million people, and 15% of runoff. In the 'new areas' of Germany (the former eastern portion), 72.5% of the population is connected to sewage systems and 58% is connected to a sewage treatment plant. Much of the industrial wastewater, however, has no treatment at all. Eighteen percent of observation wells are polluted or endangered by nitrates. Fifteen percent of the or endangered by nitrates. Fifteen percent of the drinking water supply is usable with conventional treatment and 38% is usable with advanced treatment, but 47% is unusable. Ninety-three percent of the population (15 million) is connected to a public water supply, but 7.6 million receive drinking water that does not meet all standards. Water and sewage agencies have been restructured into pri-vate form (joint stock companies, limited companies). Priorities have been set to update the out-moded technology and to improve water quality. moded technology and to improve water quanty. Some pollution standards (e.g., cadmium, lead, nitrate, iron, and pesticides) have been suspended for periods varying from 1-5 yr because it is impossible to achieve immediate compliance. Microbiological requirements will be attained first, ultimately reaching the microgram level. (Rochester-PTT) W91-11272

Separation Science and Technology SSTEDS, Vol. 25, No. 13/15, p 1387-1406, 1990. 6 fig, 10 tab,

Descriptors: \*Boiler water, \*Desalination, \*Electrodialysis, \*Industrial water, \*The Netherlands, \*Water treatment, Ion exchange, Separation tech-

Due to the high expense of tap water in some parts of the Netherlands, the use of treated surface water as boiler make-up water was investigated using an electrodialysis reversal process. Pilot scale studies were carried out using water from the North Sea Canal and Rhine River. Pretreatment of the surface water to remove suspended matter was per-formed by simple filtration with a multi-media filter or a sand filter followed by filtration with an activated carbon filter to remove oily substances.

Desalination was by electrodialysis reversal. Posttreatment was by means of ion exchangers to remove residual salts, silicate and organic compounds. During the operating period, no mem-brane fouling occurred with either canal or river water. Economic evaluations based upon the situa-tion of a powerplant located at the North Sea Canal indicated a pay back period for an installa-tion with a production capacity of 20 cu m/hr of about 6.5 yr. EVALUATING AERATION TECHNOLOGY FOR RADON REMOVAL. American Water Works Service Co., Voorhees,

K. L. Dixon, R. G. Lee, J. Smith, and P. Zielinski. Journal of the American Water Works Association JAWWA5, Vol. 83, No. 4, p 141-148, April 1991. 8 fig. 11 tab, 13 ref.

Descriptors: \*Aeration, \*Radon, \*Water treatment, \*Well water, Comparison studies, Mainte-nance, Packed tower aeration, Pennsylvania, Per-formance evaluation, Spraying, Wells.

Spray jet aeration, packed tower aeration, and multistaged bubble aeration were evaluated for the removal of radon from water, using water drawn from wells in service districts of the Pennsylvania-American Water Company. The spray jet aeration system did not exceed 75% radon removal; variations in air-to-water ratio had a negligible effect on radon removal efficiency and the orifices of the on radon removal efficiency and the orifices of the spray jet unit are susceptible to clogging resulting decline in removal efficiency. Frequent maintenance of the unit is indicated. For these reasons, the spray jet unit is not considered suitable for radon removal applications. Packed-tower aeration was found to be a very effective and flexible mechanism for radon removal, with removal efficiency was largely a function of packing height. Based on experience to date, maintenance of packed towers is expected to be minimal, but because of its relatively high profile, a PTA may not be suitable in communities where esthetics are a primary con-cern. The multistaged bubble aeration system is a effective and flexible means of radon remov al. Current design limits the system to wells with al. Current design limits the system to wells with capacities of 800 gpm or less if removal efficiencies >95% are necessary. For systems requiring lower removal efficiencies (<85%), the current design is capable of treating up to 1,800 gpm. Minimal maintenance is expected with this system ado because the units can be enclosed within a well house, they may be particularly suited to sites where esthetics are of primary concern. IMPACT OF CHANGING REGIONAL EMIS-SIONS ON PRECIPITATION CHEMISTRY IN THE EASTERN UNITED STATES.

New York Botanical Garden, Bronx, NY. Inst. of Ecosystem Studies

T. J. Butler, and G. E. Likens.

Atmospheric Environment ATENBP, Vol. 25A, No. 2, p 305-315, 1991. 4 fig, 3 tab, 44 ref. DOE contract no. DE-FG02-88ER60292.

Descriptors: \*Acid rain, \*Chemistry of precipita-tion, \*Nitrogen oxides, \*Precipitation, \*Sulfur di-oxide, \*Water pollution prevention, \*Water pollu-tion sources, Air pollution, Illinois, New Hamp-shire, New York, Ohio, Pennsylvania, Sulfates.

From 1975 to 1987 a 19% change in SO2 emissions and a 16% change in NOx emissions have occurred over the eastern and mid-western U.S. Six continental precipitation chemistry sites from the MAP3S network, plus the Hubbard Brook Experiment Forest, NH, show a direct relationship between emission levels and precipitation H(+) and SO4(2-) concentrations, except for Penn State, PA. MAP3S sites at Illinois and Ohio, located closest to MAP3S sites at Illinois and Ohio, located closest to the major SO2 source regions, demonstrate statistically significant linear regressions of SO4(2-) concentrations on SO2 emissions. Whiteface Mountain, NY, shows a weaker relationship, and Hubbard Brook shows the strongest relationship between SO2 emissions and SO4(2-) concentration in precipitation. No site shows a significant relationship for NOx emissions and NO3(-) concentrations in precipitation. Illinois, Ohio, Ithaca and Hubbard Brook show significant linear repressions of H(-1) Brook show significant linear regressions of H(+) concentrations on emissions of SO2 + NOx. Overconcentrations on emissions of SO2 + NOx. Overall, for the entire region examined, decreasing SO2 emission levels appear to have decreased  $SO4(2\cdot)$  concentrations with an efficiency of 74% + /+15%. Decreasing SO2 plus NOx emissions (18%) have been accompanied by a decreasing H(+) concentration (18%) suggesting an efficiency of conversion of 100% + /-15% for the study region as a whole. While significant reductions in acid species have occurred at Hubbard Brook, further reductions in excess of 50% of present deposition are necessary to protect acid-sensitive ecosystems. (Author's abstract) W91-10473

PROPERTIES OF LINEAR PROGRAMMING MODELS FOR ACID RAIN ABATEMENT. Meteorologischer Dienst der DDR, Potsdam

Atmospheric Environment ATENBP, Vol. 25A, No. 2, p 401-410, 1991. 7 fig, 4 tab, 11 ref.

Descriptors: "Acid rain, "Air pollution control, "Computer programs, "Cost analysis, "Model studies, "Water pollution prevention, Computers, Deposition, Linear programming, Mathematical studies" ies, Optimization, Sensitivity analysis.

Several properties were established for linear programming problems arising in the field of acid rain abatement (in the case of a linear source-receptor relationship and linear or piecewise-linear abatement cost functions). In the optimal solution, the number of sources that are not at an inflection point of the corresponding piecewise-linear cost function is equal to the number of binding environmental constraints. (Here inflection point denotes a noint where the piecewise-linear cost function mental constraints. (Here inflection point denotes a point where the piecewise-linear cost function changes its slope; an environmental constraint is called binding if, for the optimal solution, the calculated deposition is just equal to, and not less than, the constraint.) As a consequence, several sources have optimal memissions that get stuck at an inflection point. This influences the results of sensitivity analyses as well as the numerical accuracy of the optimal solution (if the piecewise-linear cost function has been obtained as a coarse approximation to a more complicated cost function). Moreover, for targets becoming more stringent, the optimum abatement costs may decrease for certain sources, although the total abatement costs increase. This rather unexpected effect indicates that pure optimization results should be applied that pure optimization results should be applied (for example, in negotiations) in a careful manner. For 40 years, mustard gas, napalm, and pesticides were manufactured just 10 miles from downtown Denver at the Rocky Mountain Arsenal. Much of the chemical wastewater flowed to a 93 acre, 243 million gallon pond, built in 1956, creating a potent and unusual mixture of water, organics and dis-solved solids. A decade of studies and pilot pro-grams has finally lead to remediation through the use of a downfired liquid incinerator. Submerged quench incineration was chosen because it could completely destroy the highly sensitive organic components. The equipment can also continually purge itself of approximately 1,500 pounds/hour of salt and heavy metals; withstand the corrosive activity of the dissolved solids; and process very high amounts of ammonium nitrogen. During the community involvement program, area residents repeatedly questioned the fate of the incinerator's repeatedly questioned the late of the incherator's product brine. The brine was initially supposed to be dried and disposed of in an off-site landfill. In a significant decision, the EPA, the Army and the state of Colorado agreed to amend the incinerator program to include shipping of the liquid to an off-site commercial facility, which will remove the metal components by precipitation and recycle them at a commercial metals operation, leaving nothing to be disposed of on land. The only re-maining product will be clean salt water, free of both hazardous organics and toxic metals, to be discharged to a coastal salt-water receiving body.

No. 4, p 72-73, April 1991.

Descriptors: \*Groundwater pollution, \*Water pollution control, \*Water quality, Agricultural chemi-cals, Environmental protection, Groundwater, Groundwater management, Industrial wastes, Landfills, Public policy, Safe Drinking Water Act, Septic tanks, Superfund, Underground storage tanks, Water conservation, Water law.

In spite of historical tendencies toward complex surface-water projects and a political climate that has spawned disincentives to conserve water and develop it economically, the world is at last on the right track toward balancing its water budget. Commonsense management techniques are the key to such a balance. Environmental protection is advancing as fast as possible, given current resources and the fact that such progress is locked into the pace of scientific, technical and institutional development. But politicians can demand an instant end to long-standing problems. They can promise more than any government agency can reasonably deliver. Groundwater has been protected through the amended Water Pollution Control Act of 1972, the Safe Drinking Water Act of 1974, half a dozen later acts and Superfund. Meeting the public's expectation of environmental cleanup is public's expectation of environmental cleanup is impossible. The risk has been distorted, and analytimpossible. The risk has been distorted, and analytical techniques are just too good. The public wants everything out, but tests will soon show contaminants in concentrations as low as a part per quadrissed in the past five years: landfills, agricultural chemicals, industrial waste lagoons, underground storage tanks, leaking pipelines, septic tanks and highway salting. Although the glacially slow movement of groundwater produces long-term problems, it also affords adequate time to achieve the most reasonable approach to managing these residual problems of the past. Groundwater contamination is an increasing problem, especially in large urban areas. Toxics that seep into water supplies threaten the health of the community, but engineers have various options at their disposal to deal with the problem. Remediation options include containment and physical, chemical and biological treatment. Containment techniques include impermeable and hydraulic bar-riers, and surface water and leachate controls. Impermeable barriers that contain, capture or redirect permeable barriers that contain, capture or redirect groundwater flow may be slurry walls, grout cur-tains or sheet pilings. Inexpensive slurry walls are the most common type. Surface water and leachate control systems manage surface water flows at waste disposal sites. System types include dikes, berms, terraces and benches to prevent or intercept runon/runoff; channels, waterways, chutes and downpipes to collect and transfer water; seepage basins and ditches to store and discharge it; and sedimentation basins and ponds. Physical treatment depends on the volatile, adsorptive and/or insolu-ble properties of the contaminant. Types include phase-separated hydrocarbon recovery, air strip-ping, activated carbon adsorption and filtration. Chemical treatment of groundwards mical treatment of groundwater includes coagulation-precipitation, redox reactions and neu-tralization. Biological treatment involves the microbial degradation of organics in a waste system. It is routinely used to remove organics from municipal and industrial wastewater, and can be used to treat groundwater that contains moderate levels of organics. Although biodegradation occurs in both aerobic and anaerobic environments, aerobic biotreatment is more common. Biotreatment techpiotreatment is more common. Biotreatment techniques applicable to hazardous wastes include activated-sludge processes and fixed-film processes such as rotating biological contactors and trickling filters. (Mertz-PTT) W91-10486

MATHEMATICAL MODELLING FOR RESERVOIR WATER-QUALITY MANAGEMENT THROUGH HYDRAULIC STRUCTURES: A CASE STUDY.

ENGE-RIO, Engenharia e Constuloria S.A., Rio

ENGE-RIO, Engenharia e Constutoria S.A., Rio de Janeiro (Brazii). M. C. Araujo Filho, J. A. O. De Jesus, J. M. Branski, and J. A. Macari Hernandez. Ecological Modelling ECMODT, Vol. 52, No. 1/ 2, p 73-85, November 1990. 6 fig, 3 tab, 7 ref.

Descriptors: \*Computer models, \*Model studies, \*Reservoir operation, \*Tropical regions, \*Water quality control, Amazon River, Hydraulic structures, Hydroelectric plants, Hydrologic models,

The U.S. Army Corps of Engineers' one-dimensional model (CE-QUAL-RI) was used to analyze the usefulness and feasibility of hydraulic structures in allowing management procedures for reservoir water-quality control. The model calculates the vertical hydrothermal and water-quality structure are fraction of inflowing waters meteoralthe vertical hydrothermal and water-quality struc-ture as a function of inflowing waters, meteorol-ogy and reservoir operation. It considers selective withdrawal as a result of the operation of spill-ways, intake for turbines and bottom outlets. The feasibility of a bottom outlet in altering water-quality tendencies of an Amazon hydroelectric quality tendencies of an Amazon hydroelectric power project (Cachoeira Porteira Reservoir) whose the filling is forecast for first half of 1995 was examined. In order to obtain more realism in respect to water-quality dynamics of Amazon reservoirs, some modifications were introduced to the original model version, which was also adapted to 16-bit microcomputer hardware. A large hydrological series of averaged monthly flow rates was studied and two semential years were chosen for studied, and two sequential years were chosen for obtaining a critical reservoir water-quality situa-tion. Field water-quality data from distinct hydrological periods were used, and daily local meteoro-logical information was considered. The simulations involved four hypotheses, with consideration of different flow rates through a bottom outlet. The alterations to reservoir water-quality tenden-cies were analyzed, emphasizing the intensity of cres were analyzed, emphasizing the intensity of stratification, eutrophication, and anoxic conditions caused by the flooding of natural vegetation. The results show the low influence of bottom outlet utilization in the specific case of Cachoeira Porteira Reservoir water quality. (Author's abstract)

The Food, Agriculture, Conservation, and Trade Act (FACTA) of 1990, commonly called the 1990 farm bill, will form the statuatory foundation of U.S. agricultural policy for much of the coming decade. The law covers all of the traditional agricultural policy topics, from commodity price and income present to agricultural trade and from income support to agricultural trade, and from food stamps to research. Fourteen of FACTA's 25

titles deal directly with some aspect of natural resource conservation, environmental protection, or consumer issues. The Congress not only reau-thorized and modified the landmark 1985 Conservation Title, it also enacted new provisions dealing vation Itue, it also enacted new provisions dealing with water quality, pesticides, organic food, sustainable agriculture research, global warming, and other environmental topics. Title XIV of FACTA makes highly erodible set-aside land subject to conservation compliance; it also expands the list of programs to which compliance is tied. Concern programs to which compliance is tied. Concern about degradation of groundwater and surface water from farming activities dominated the 1990 farm bill. The most notable provision is the new Agricultural Water Quality Protection Program. This provision emphasizes water quality protection, including source reduction of agricultural pollutants. Furthermore, agricultural producers in environmentally sensitive areas should request assistance to develop and implement on-farm water maslity protection plans in order to assist in community protection plans in order to assist in comquality protection plans in order to assist in com-pliance with State and Federal environmental laws and to enhance the environment. Formulation and implementation of an integrated coastal area management plan in Lingayen Gulf, Philippines is necessary in light of increasing conflicts in use, resource depletion and degradation of water quality. Lingayen Gulf, a semi-enclosed body of water located in the northern part of the Philippines is a major fishing and tourist area in the country. The gulf is the catchment basin of major rivers in the region and consequently of the pollut-ants within the immediate vicinity. Pollution coming from point and non-point sources includes high levels of microbes from domestic sewage, fertilizers and pesticides from runoff, trace metals from mining activities, and siltation and sedimenta-tion from logging and mining operations and ex-plorations. Proposed solutions include the preparation of a master plan for a sewerage system; water unit of a master pair for a sewcage system, water quality monitoring of the six major river systems discharging in Lingayen Gulf; surveillance, en-forcement and monitoring of mining operations within the Baguio Mining District; epidemiological monitoring; establishment of a pilot solid waste disposal system for urban centers an upper water-shed management and rehabilitation plan an inforcampaign on environmental protection; and a training program to upgrade the technical capability of the research institutions and regulatory agencies within Lingayen Gulf. Primary production in eutrophic water bodies contributes to water pollution, in the form of organic pollution. In order to evaluate the organic pollution load originated from primary production in an enclosed water body (the internal organic pollution load), many methods for evaluation have been proposed. Though strict evaluation of the internal organic pollution load is difficult, its approximate evaluation is possible. For the control of this interevaluation is possible. For the control of this mer-nal organic production, the reduction of inflowing nutrient levels, the eutrophic potential in each sea area is calculated with a simple procedure. Though nutrients are essential for biological production, their excess creates many water quality problems. Therefore, for the control of nutrient impacts to the enclosed coastal seas in Japan, the following strategies are proposed: (1) an effective measure for nutrient load reduction in their primary stage, for nutrient load reduction in their primary stage, as a consequence of structural analysis of nutrient budgets in Japan; (2) waste water treatment for nutrient load reduction; and (3) appropriate distribution of nutrient load impact based on the eutrophic potential of each coastal sea and each adjacent sea of Japan. The sewer and sewage treatment system is an effective system for reduction and distribution of the nutrient load. (Author's abstract) W91-10524

NORTH SEA STRATEGIES. Ministry of Transport and Public Works, The Hague (Netherlands). Tidal Waters Div. P. H. A. Hoogweg, K. J. Wulffraat, and B. G. M. van de Wetering. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 57-61, 1991. 3 fig, 2 tab, 4 ref.

Descriptors: \*Marine fisheries, \*Marine pollution, \*Marine transportation, \*North Sea, \*Path of pollutants, \*Resource allocation, \*Water pollution control, \*Water pollution sources, \*Water resources management, Chlorinated hydrocarbons, Ecosystems, Heavy metals, Pesticides, Regulations, Suspended solids, The Netherlands, Turbidity, Wetlands

The North Sea, with an area of about 575,000 sq km, has the most intensive traffic of any sea in the world, and fisherman land three billion kilograms of fish every year. While the Dutch coasts have valuable wetlands, thousands of tons of heavy metals, chlorinated compounds, nutrients and pesticides are emptied into this area every year. Turbid-ity in the North Sea has increased with increased suspended matter, damaging the ecosystems of the region. The overfishing (capture of nearly 25% of the total fish stock) every year makes the fishery non-sustainable. Due to the multifaceted use of the North Sea, sustainable development through regu-lation and future planning for reduction of pollu-tion loads and fishing levels will allow for contin-ued use of this resource. WATER QUALITY ASSESSMENT AND PRO-TECTION MEASURES OF A SEMI-ENCLOSED COASTAL AREA: THE BAY OF THERMAIKOS (NE MEDITERRANEAN SEA).

Thessaloniki Univ., Salonika (Greece). Lab. of Hydraulics and Hydraulic Works.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 83-87, 1991. 7 fig, 4 ref.

Descriptors: \*Greece. \*Marine pollution. \*Medi-\*Thermaikos Bay, \*Water pollution control, Coliforms, Industrial wastes, Model studies, Municipal wastes. Nutrients.

Twelve stations were sampled, over the time period 1984 to 1990, to monitor the water quality in the Thermaikos Bay area, Greece. The northern part of the bay, with a total surface area of 300 sq km and maximum depth of 30 m, is heavily pollut-ed by untreated sewage from the city of Thessaloniki and by industrial effluents. At all twelve sta-tions, temperature, salinity, pH, dissolved oxygen, nitrites, nitrates, ammonia, phosphates, silicates, heavy metals, total coliforms and Escherichia coli were measured in the water column in each season. Water pollution tends to increase from south to north and from the open sea to the estuaries of the Axios and Gallikos Rivers, reflecting river flow and the pollutant loads from human population in the northern region. The water-quality data used for assessing the environmental situation were employed to calibrate mathematical models which were then used to explore the efficiency of remedi al measures for the Bay of Thermaikos. Because of environmental concerns about water quality in the Axios River and the sea, operation of the new Thessaloniki city sewage system has been delayed for a year. It has been decided to impose further biological treatment of the wastewater. Meanolonogical treatment of the wastewater. Mean-while, discharge to the upper part of the Bay of Thermaikos is planned, using a ditch parallel to the Gallikos River. Mathematical modeling was used to study local environmental impacts in this area, especially concentrations of coliforms. (Brunone-PTT) W91-10534

SEAGRASS-MANGROVE ECOSYSTEMS MAN-AGEMENT: A KEY TO MARINE COASTAL CONSERVATION IN THE ASEAN REGION. Philippines Univ., Diliman, Quezon City. Marine

ce Inst. M. D. Fortes.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 113-116, 1991. 21 fig.

Descriptors: \*Coastal environment, \*Coastal zone management, \*Conservation, \*Ecosystems, \*Envimanagement, Conservation, Ecosystems, Edityronmental policy, "Managrove swamps, "Sea grasses, "Water pollution control, Aesthetics, Economic aspects, Education, Erosion, Fisheries, Research, Sedimentation, Water resources management, and the search of th

Seagrass beds and mangrove forests are intimately linked by functional interactive processes which are as yet little understood. These high-order interactions form a major basis which justifies an inte-grated management scheme for the two ecosys-tems. However, while dominating enclosed coastal tems. However, while commaning encrosed coasial areas in the ASEAN region, sea grass and mangrove habitats are being degraded and destroyed at an alarming rate, raising serious doubt on their capacity for biological sustainability and normal recovery within this generation. An integrated approach toward seagrass and mangrove ecosystems management in the ASEAN region is outlined within a framework of known ecological principles. Proposed goals for seagrass and mangrove ecosystem management in the Philippines include the preservation of natural interconnections known in the ecosystems; protection of ecologically valuable and economically harvestable fisheries; protection of the coastline from erosion, siltation and pollution; establishment of seagrass and mangrove reserves for research and educational purposes; and preservation of aesthetic and recreational qualities of the natural shorelines. USE OF RESPIRATION IN THE SANDY BEACH OR ON THE TIDAL FLAT: 1, PERME-ABLE SANDY BEACH. Shin Nippon METOCEAN Consultant Co., Ltd., Edobori 3-2-23, Nishi-ku, Osaka, 550 Japan.

I. Sakamoto.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 123-130, 1991. 12 fig, 4 tab, 6 ref.

Descriptors: \*Beaches, \*Cleanup, \*Fate of pollutants, \*Respiration, \*Sediment-water interfaces, \*Site remediation, \*Water pollution treatment, Aerobic conditions, Bacteria, Microbial degradation, Mineralization, Sediment chemistry, Tidal

There are two types of beach respiration: the sandy beach type, in which air and seawater mix in the interstices of a permeable soil; and a tidal flat type, in which air and seawater mix on the surface of a nonpermeable soil. Both types are accordanced. of a nonpermeable soil. Both types are noted for the aerobic decomposition of rapidly mineralizing organic materials brought in by flood-tide water in the natural system. Sandy beaches are effective for the natural system. Sandy beaches are effective for the removal of dissolved organic loads, while tidal-flat beaches are more effective for trapping suspended particulates. Sandy beach respiration is carried out by microorganisms adhering to sand particles, while tidal flat beach respiration is carried out by burrowing macroinvertebrates. Study of the respiratory function of beaches has been intensified because of concerns about coastal water quality. It has been observed that heavy oils which drift ashore and are buried in sandy beaches are adsorbed on the sand grains and decomposed in situ. This phenomenon might be employed for the resorted on the sand grains and decomposed in stu.
This phenomenon might be employed for the remediation of accidental oil spills, using natural
beach sands. A further environmental benefit of
natural sandy beaches is in the final purification of effluents discharged from activated-sludge-process wastewater treatment facilities. Tidal rise and fall ensure periodic exposure of the partially-treated water to the natural bacterial ecosystem on the sand grains, and maintain aerobic respiratory conditions by periodically exposing the ecosystem to the atmosphere. SUMMARY OF PORTS AND MARINE ENVI-RONMENT IMPROVEMENT WORK AND EX-AMPLE OF LATEST MEASURES IN SETO INLAND SEA.

Ministry of Transport, Kobe (Japan). 3rd District struction Bureau.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 149-153, 1991.

Descriptors: \*Coastal zone management, \*Harbors, \*Japan, \*Marine pollution, \*Seto Inland Sea, \*Water pollution control, \*Water resources management, Chemical oxygen demand, Eutrophica-tion, Path of pollutants, Regulations, Sediment contamination, Site remediation.

Port and marine environmental improvement work in Japan began with the construction of waste oil disposal facilities in 1967 and port pollution prevention work in 1972. In the port and harbor areas of the Seto Inland Sea, transport and production of goods is extensive, resulting in increased inflow of goods is extensive, resulting in increased inflow of pollutants and environmental pollution. A plan for 'Ports in the 21st Century' was developed in 1985, calling for limiting of the functions of ports. Clean-up operations began in the early 1970's to remove floating refuse and oil in the inner seas and bays, noating retuse and oil in the inner seas and bays, such as Tokyo Bay, Ise Bay, and the Seto Inland Sea, under supervision of the government. At present, emergency dispatch systems for inland sea pollution are supervised by the District Port Construction Bureaus and the Maritime Safety Agency. In areas that are enclosed and have large cities located on their shores (such as the Seto Inland Sea), despite the implementation and strengthening of regulations governing effluent production from domestic and industrial sources on land, the situation has not improved. Red tides caused by eutrophication are still a common occurrence, as are bathing restrictions. Effective control measures include cleanup of the sea bottom, since organic pollutants can be dissolved into seawater from sludge. By covering the polluted sea bed with sand, bottom COD-containing areas were greatly reduced, and the numbers and wet weight of benthos increased. (Brunone-PTT)

RECOVERY OF AQUATIC ANIMALS IN DOKAI BAY, NORTHERN KYUSHU, JAPAN. Kitakyushu Municipal Inst. of Environmental

Health Sciences (Japan). M. Yamada, R. Takeuchi, S. Sueta, K. Kido, and

Y. Yabumoto.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 201-207, 1991. 3 fig, 1 tab, 10 ref.

Descriptors: \*Dokai Bay, \*Japan, \*Marine animals, \*Marine fisheries, \*Resource recovery, \*Water pollution control, Biological samples, Commercial fishing, Shrimp, Species composition, Surveys, Water pollution effects.

Dokai Bay, in northern Kyushu, Japan, used to be an excellent area for catching Kuruma prawn, with maximum landings recorded in 1928. Heavy water pollution from untreated domestic and industrial waste waters in Kitakyushu has caused widescale mortality of marine organisms. The fishermen of Dokai Bay had caught few fish since 1943. Since then, due to a successful attempt to decrease inflow of waste waters, the water quality of the bay has improved and commercial fishing of Kuruma prawn started again in 1983. Since 1988, aquatic animals have been sampled using gill nets and a small trawling net. One hundred and fifteen species of aquatic animals have been collected in these surveys: 65 species of fish, 37 species of arthropods, 12 species of mollusks, and 1 species of echinoderm. Almost all of these species were coastal-temperate species, and some were the same species reported in surveys before the pollution increase. Abundant species included Kuruma prawn, hardback shrimp, mantis shrimp, common goby, streaked goby, black porgy, and gizzard shad. Aquatic animals collected were abundant at all times of the year except in the summer at the inner part of the bay. Several species which had disappeared or were on the verge of extinction in 1933 were found in this recent survey. (Author's abstract)

STUDY ON MODEL REFERENCE ADAPTIVE WATER POLLUTION CONTROL IN ENCLOSED COASTAL SEA.

Hokkaido Univ., Sapporo (Japan). Graduate School of Environmental Science.

E. Yamamura, and M. Ota.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 379-382, 1991. 4 ref.

Descriptors: \*Coastal waters, \*Economic development, \*Marine pollution, \*Mathematical models, \*Model studies, \*Path of pollutants, \*Water pollution control. Comparison studies.

For pollution control in an enclosed coastal sea, the relationships were investigated between the economic activities on land and ecological activities in the enclosed coastal sea. Using Hermite Inverse Matrix Analysis, the balance of inter-field repercussions are shown through the total effects of inter-field propagation. Furthermore, to attain model reference pollution reduction, paths were evaluated which converge to the reference model. The adaptation processes of a system and its stability were tested by using Model Reference Adaptive Input-Output Methods. This model demonstrates the convergence between the reference model and the field results. (Author's abstract)

STRATEGIES FOR RESTORING AND DEVEL-OPING FISH HABITATS IN THE STRAIT OF GEORGIA: PUGET SOUND INLAND SEA, NORTHEAST PACIFIC OCEAN.

Department of Fisheries and Oceans, Vancouver (British Columbia). West Vancouver Lab.

C. D. Levings.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p
417-422, 1991. 1 fig, 22 ref.

Descriptors: \*Biotechnology, \*Coastal waters, \*Fisheries, \*Habitat restoration, \*Puget Sound, \*Strait of Georgia, \*Wetlands, Algal growth, Aquatic habitats, Environmental impact, Environmental monitoring, Industrial development, Riparian areas, Sea grasses, Sedges, Water quality monitoring.

Fish habitat rehabilitation and development in enclosed coastal seas is a relatively new branch of biotechnology that clearly requires further research. Rehabilitation and development of fish habitats are potential techniques for achieving sustainable development in coastal seas. Recent projects in the Strait and Puget Sound have used experiments with sedge marshes (Carex lyngbyei) in 26 sites and eelgrass beds (Zostera marina) in 14 sites. Some studies were appropriate for examining the potential compensation of wetland losses from industrial developments, but many were experimental and small-scale. More information is needed on the relative functional values of habitats such as sand and mud flats, algae beds, and riparian areas. Larger scale projects and longer term monitoring are needed to confirm that the policy goals of no net loss or net gain in fish habitat can be met using these techniques. (Brunone-PTT)

COUNTERMEASURES AGAINST WATER POLLUTION IN ENCLOSED COASTAL SEAS IN JAPAN.

Environment Agency, Tokyo (Japan). Water Pollution Control Div.

T. Hisano, and T. Hayase. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 479-484, 1991. 4 fig, 2 tab.

Descriptors: \*Coastal waters, \*Enclosed seas, \*Japan, \*Pollution load, \*Water pollution control, \*Water pollution sources, Anoxic conditions, Aquatic animals, Aquatic plants, Chemical oxygen demand, Eutrophication, Industrial wastewater, Mortality, Nutrient concentrations, Regulations, Seasonal variation, Species diversity, Tokyo Bay, Water exchange, Water quality standards, Water resources management.

Careful attention is necessary to control the water quality of enclosed water bodies such as inner seas and bays, because they have little ability to exchange water with the open sea and pollutants are easily accumulated. In Tokyo Bay, which receives many sources of inland pollution, organic pollution is conspicuous. Many kinds of benthic organisms living at the bottom of the inner part of the bay decrease in the summer, when a thermocline is formed. Anoxia is considered to be closely related to this increased mortality. The amount of pollution load from industrial sources has been decreasing as a result of implementing stringent effluent controls, such as setting up areawide total pollutant load control standards establishing maximum permissible limits of pollutant loads derived from industry. However, to further improve water quality, further efforts must reduce the total pollutant load. To reduce eutrophication in these water bodies, the nutrient load as well as the COD load must be reduced. In 1978, the law concerning Special Measures for Conservation of the Seto Inland Sea was set up, which includes new provisions for the prevention of the cocurrence of damage from eutrophication. (Brunone-PTT)

### Water Quality Control—Group 5G

ENVIRONMENTAL MANAGEMENT OF THE SETO INLAND SEA.

Hyogo Prefectural Public Health and Environment Dept., Kobe (Japan). H. Yasui, and E. Kobayashi.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 485-488, 1991.

Descriptors: \*Inland seas, \*Japan, \*Seto Inland Sea, \*Water pollution control, Conservation, Economic development, Environmental monitoring, Human population, Industrial development, Population density, Wastewater pollution.

The Seto Inland Sea, the largest inland sea in Japan, is known for its scenic beauty. Since ancient times, the Seto Inland Sea has served as a transportation route, bringing about cultural and industrial development. However, high population density and industrial development led to an increase in wastewater, causing the Seto Inland Sea environment to deteriorate to the extent that, by the 1970's, the sea appeared to be dying. Alarmed by worsening environmental conditions, concerned governors and mayors established in 1971 the Governors' and Mayors' Conference on the Environmental Protection of the Seto Inland Sea. In 1978, this conference took a leading role in enacting the Extraordinary Law Concerning Special Measures for the Conservation of the Environment of the Seto Inland Sea. At the same time, the prefectures and cities jointly financed and established the Seto Inland Sea Environmental Association, to disseminate knowledge relating to environmental conservation in the Seto Inland Sea. This association has been actively involved in environmental conservation in compliance with this conservation objective. (Author's abstract)

INTERNATIONAL PROGRAMME FOR THE PROTECTION OF A SEMI-ENCLOSED SEA: THE MEDITERRANEAN ACTION PLAN.

United Nations Environment Programme, Athens (Greece). Co-ordinating Unit for the Mediterranean Action Plan.

A. Manos.
Marine Pollution Bulletin MPNBAZ, Vol. 23, p
489-496, 1991. 1 ref, 4 append.

Descriptors: \*Coastal waters, \*Environmental monitoring, \*International agreements, \*Mediterranean Sea, \*Water pollution control, Air pollution control, Ballast water, Desertification, Endangered species, Human population, Legal aspects, Marine pollution, Outfall, Population density, Regulations, Waterwater treatment facilities, Water pollution

The United Nations Conference on the Human Environment included the protection of the oceans against pollution among the priorities for international action. The Mediterranean Action Plan was launched under the auspices of the United Nations Environmental Programme, coordinating the efforts of eighteen coastal states and the European Economic Community. The Action Plan has four components: socio-economic, aimed at identifying the causes of pollution and the methods readily available for pollution reduction; scientific, aimed at collecting valid, comparable data on priority pollutants, as a basis for legal and other measures; legal, that would commit coastal states to an active program, going beyond mere declarations; and institutional, to ensure the continuity of action with funds earmarked. Also included are the specific quality criteria, emission standards and other measures already adopted by the Mediterranean States. Ten targets have been specifically set, including the establishment of reception facilities for dirty ballast water and other oil residues received from tankers and ships in ports of the Mediterranean; establishment of sewage treatment plants in all cities around the Mediterranean with more than 10,000 inhabitants; applying environmental impact assessment to ensure proper development activities; cooperation to improve the safety of maritime navigation and to reduce the risk of transport of toxic substances likely to affect the coastal area or to induce marine pollution; protection of endan-

### Group 5G-Water Quality Control

gered marine species; reduction in industrial pollution and disposal of solid waste; preventing and combatting forest fires, soil loss, and desertifica-tion; and reducing air pollution which adversely affects coastal areas and the marine environment with the potential danger of acid rain. ENVIRONMENTAL RESEARCH, POLICY AND REGULATION: THE CHESAPEAKE BAY AND REGULATE EXPERIENCE.

Maryland Univ., Cambridge. Center for Environ-mental and Estuarine Studies. T. C. Malone, and W. H. Bell. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 497-501, 1991. 1 tab, 5 ref.

Descriptors: \*Chesapeake Bay, \*Coastal waters, \*Environmental impact, \*Environmental law, \*Environmental law, \*Environmental law, \*Environmental policy, \*Regulations, \*Water pollution prevention, Public policy.

Current efforts to manage the environmental impacts of human activities tend to focus on symptoms of environmental stress rather than on underlying causes. Given the need for immediate action, a distinction must be made between short-term, tactical responses to indicators of stress and long-term, strategic solutions based on a theoretically sound understanding of ecosystems and the role of the human species in ecosystems. The formulation of environmental policy and management plans for coastal seas must be based on information generated by environmental research that is independent ed by environmental research that is interpendent of government agencies responsible for policy and management and special interest groups that have environmental agendas. Chesapeake Bay is an ex-ample of the relevance of independent research to coastal seas governance and the importance of clearly defined roles and relationships among research institutions and government agencies. The Chesapeake Bay Program embodies two of the major ingredients required for a comprehensive coastal seas' governance initiative: the recognition that environmental management must reconcile the immediate need to respond to the symptoms of environmental stress with the ultimate requirement for a fundamental understanding of the effects of human activities; and a holistic view of environmental management based on the principle that a healthy environment and economic development are interdependent. (Brunone-PTT) W91-10575

NON-REGULATORY APPROACHES TO MAN-AGEMENT OF COASTAL RESOURCES AND DEVELOPMENT IN SAN FRANCISCO BAY. California State Coastal Conservancy, Oakland. For primary bibliographic entry see Field 2L. W91-10576

ENVIRONMENTAL MANAGEMENT OF THE PUGET SOUND.

Puget Sound Water Quality Authority, Seattle, WA. N. McKay. Marine Pollution Bulletin MPNBAZ, Vol. 23, p

509-512, 1991. 5 ref.

Descriptors: \*Environmental impact, \*Estuaries, Puget Sound, \*Water pollution control, \*Water quality control, \*Water resources management, Economic aspects, Legal aspects, Storm water, Wastewater pollution, Wetlands.

Puget Sound shows a characteristic estuarine circulation pattern. The Sound is showing symptoms of poor resources management, with multiple industrial and domestic sources contributing to the growing amount of waste entering the waters.
Through the establishment of the Puget Sound
Water Quality (PSWQ) Authority, the national Water Quality (PSWQ) Authority, the national setuary program has been implemented, designed to address comprehensively pollution from all sources and require all sources to share responsibility for improving water quality. The PSWQ Management Plan has thirteen programs: municipal and industrial discharges, contaminated sediments and dredging, oil spill prevention and response, storm-

water and combined sewer overflows, nonpoint water and combined sewer overflows, nonpoint source pollution control, shellfish protection, wet-lands protection, laboratory support, household hazardous waste, monitoring, research, education and public involvement, and legal and personnel support. Full implementation of this plan would cost about \$27 million/yr. (Brunone-PTT) W91-10577

SEA AND FRESH WATER CONSERVATION. Osaka Prefecture Water Works Bureau (Japan). K. Hattori, Y. Inoue, and T. Okumura. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 519-523, 1991. 6 fig, 4 ref.

Descriptors: \*Japan, \*Seawater, \*Water pollution control, \*Water quality control, \*Water quality standards, Ammonia, Biological oxygen demand, Human population, Land use, Mathematical models, Nutrient concentrations, Organic carbon, Osaka Bay, Precipitation, Seasonal variation, Wastewater pollution, Yodo River.

Sea water qualities are closely related to river water qualities. Therefore, prevention of fresh water pollution can be important in preventing sea water pollution. The Yodo River is the biggest river in the Kinki district, flowing into the Osaka river in the Kinki district, flowing into the Osaka Bay, and provides water for industries and domestic use, serving 10 million people. Recently the water has become polluted due to rapid economic growth. Ammonia concentrations have been gradually increasing, with large seasonal differences and an annual average concentration of 1.0 mg/L. BOD annual average concentrations are about 3.0 mg/L, with no sasonal fluctuations. The Yodo River basin was geographically divided into nine watersheds for a model equation describing pollution discharge into the river, involving papollution discharge into the river, involving parameters of land use, ratio of sewage to population, precipitation, etc. Annual total organic carbon was estimated at 30,000 tons, with Lake Biwa contributing 40% and Katsura River contributing 20%. Committees for pollution control include the Yodo River Water Consultative Committee and the Yodo River Water Protection Committee. These committees are urging the construction of sewage treatment plants for improvement of effluents from industries, and homes. Control of freshwater pollution should result in effective pollution control for seawater quality. (Brunone-PTT) W91-10578

CONTROLLING EFFECT OF THE PLANNED MANAGEMENT OF THE ENVIRONMENT IN THE KAGOSHIMA BAY ON THE POLLUT-ANT LOAD

Kagoshima Prefecture Environment Preservation Center (Japan). Dept. of Information Management.

K. Yamano. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 525-531, 1991. 5 fig, 1 tab

Descriptors: \*Coastal waters, \*Coastal zone management, \*Japan, \*Kagoshima Bay, \*Pollution load, \*Water pollution control, \*Water pollution sources, Animal wastes, Chemical oxygen demand, Domestic wastes, Fish farming, Industrial wastes, Phosphorus, Regulations, Wastewater pollution, Water quality standards.

Kagoshima Bay is formed by a caldera, having an average depth of 117 m. The bay area supports a population of 850,000. The COD levels in the bay have remained constant (around 1.6 mg/L in the center of the end of the bay, and 1.3 mg/L at the center of the middle of the bay, while the phosphorus levels have increased to 30 microg/L in recent years. The Project for Controlling the Water Quality and Environment of Kagoshima Bay was established to serve as a guideline for various pollution control activities. Targets set by the Project include allowable limits of 16.1 tons/day of pollutants discharged, at or below 2.0 mg/L day of pollutants discharged, at or below 2.0 mg/L COD, and 0.030 mg/L or below for phosphorus. During Phase I of the Project, general principles for measures against miscellaneous household wastewater were instituted, recycling of livestock waste on farms was encouraged, guidelines for the cultivation of fish in the prefecture were estab-lished, factory waste regulations became stricter, the public sewer system was constructed and extended, and pollution consciousness was enhanced. Even with these measures, pollution levels have increased in the Bay. (Brunone-PTT)

INTEGRATED MANAGEMENT OF THE BALTIC SEA.

National Swedish Environment Protection Board. R. Ferm.

arine Pollution Bulletin MPNBAZ, Vol. 23, p 533-540, 1991. 7 fig, 1 tab.

Descriptors: \*Baltic Sea, \*Bioaccumulation, \*Sediment contamination, \*Water pollution prevention, \*Water pollution sources, Aquatic habitats, Brackish water, Chlorinated hydrocarbons, Ecosystems, Eutrophication, Fish, Human diseases, Industrial wastewater, Nitrogen, North Sea, Nutrient concentrations, Organic carbon, Path of pollutants, Phosphorus, Pollution load, Pulp and paper industry, Sediment chemistry, Shellfish, Toxicity, Wastewater treatment facilities, Water quality.

The Baltic Sea is one of the largest brackish water areas in the world, with very slow water exchange between the Baltic and the North Sea. As a result, between the Baltic and the North Sea. As a result, the water in the Baltic has a very long residence time, on the order of 35 to 40 years, leading to accumulation in water, sediments and biota of discharged pollutants. Urban areas contribute approximately 25% of the land-based sources of nutrient inputs into the Baltic. Installation of biological treatment systems is expected to dominate the investments in municipal treatment systems around the Baltic Sea, to remove nutrients to reduce or prevent eutrophication. The pulp and paper processing industry in Sweden and Finland is responsible for the major part of the chlorinated organic compound pollution load in the Baltic, while fertilizer production has caused heavy discharges of phosphorus and nitrogen salts and cadmium. Eutrophication is the most pronounced problem in the Baltic, although the increasing concentrations of toxic organic substances constitute an ever greater threat to the environment in the long term. Overall goals for the area include the maintenance Overall goals for the area include the maintenance of vigorous, balanced populations of naturally occurring species; the achievement of natural zoning of flora and fauna; prevention of harmful anoxic conditions; continuation of regular fishing; consumption of fish and shellfish from the area without health risks; and ensuring that pollution does not restrict the recreational value of the area. Measures must be taken to limit the quantity of these nutrings entering the sea and organic manner. these nutrients entering the sea, and organic man-made pollutants must also be reduced. (Brunone-PTT) W91-10580

ENVIRONMENTAL INFORMATION PROC-ESSING OF CLOSED BAY AREA BY REMOTE SENSING.

Descriptors: \*Coastal zone management, \*Computer programs, \*Eutrophication, \*Japan, \*Marine pollution, \*Mathematical models, \*Red tide, \*Water pollution control, \*Water quality monitoring, Chemical oxygen demand, Correlation analysis, Nutrient concentrations, Organic matter, Osaka Bay, Phosphorus, Pollution load, Spatial distribution, Tidal movement.

A red tide frequently occurs in Osaka Bay in the summer season, even though construction of a sewer system and regulation of point source pollu-

Water Quality Control—Group 5G

tion has taken place. Organic pollutant and nutrient loads transported from the interior of Osaka Bay by tidal movement causes the eutrophication bay by tidal movement causes the eutrophication in the wide area of the bay. A personal computer-based system has been developed to support policy-makers in the formulation of water quality management plans. The computer system consists of four subsystems furnished by a water quality model and an external loading model. The water quality model uses non-conservative balancing of the strength of t quanty model uses non-conservative balancing of chemical oxygen demand to meet environmental standards; and uses organic phosphorus, and inor-ganic phosphorus levels to assess eutrophication in Osaka Bay. Correlation analysis was used to group local input waters into clusters. Model limitations include: (1) inorganic phosphorus concentration values are lower in the summer than measured; (2) values are lower in the summer than measure, (c) tidal movement is dominant over diffusion in the determination of spatial distribution of pollutants in the model; and (3) the mean concentration values of the model cannot be directly compared with the observed values, because monitoring points are unevenly distributed. The computer graphics pro-vide visual information for decision-making. The system enables policy-makers to effectively solve the complex problem of technological and administrative problems, such as wide-area eutrophication control in enclosed seas. MANAGEMENT OF THE MARINE ENVIRON-MENT IN WESTERN AUSTRALIA: AN ECO-SYSTEM APPROACH. Western Australia Ministry for the Environment,

Perth.

R. J. Pearce.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p

Descriptors: \*Australia, \*Coastal areas, \*Coastal zone management, \*Domestic wastes, \*Industrial wastes, \*Water pollution control, Assimilative capacity, Drainage systems, Environmental effects, Nutrient concentrations, Pollution load, Wastewater pollution.

The Environmental Protection Authority of Western Australia (EPAWA) has the responsibility for controlling industrial and domestic waste inputs to state waters. With continued industrial developcontrolling industrial and domestic waste injuis to state waters. With continued industrial development and urban expansion to the north and south of Perth, pollutant loadings to nearshore marine environments will inevitably rise as a result of increases in industrial and domestic waste discharge, urban drainage and groundwater inflow. These increased loadings will cause additional stresses on the nearshore marine ecosystems of Perth. The EPAWA has adopted the concept of assimilative capacity as a philosophical approach to maintain the biological integrity of nearshore coastal ecosystems in Western Australia. This approach is based on the assumption that the receiving environment has some capacity, albeit limited, to disperse, dilute and absorb certain types of pollutants without incurring long-term damage to the biological functioning of the marine communities in question. Cockburn Sound, a marine embayment adjacent to the southern metropolitan waters of in question. Cockburn Sound, a marine embayment adjacent to the southern metropolitan waters of Perth, is an example of how this approach can be used to restore formerly severely polluted waters. The EPAWA's approach to controlling nutrient enrichment of the nearshore waters of the Perth region (which includes the Marmion Marine Park) can demonstrate how the principle of the 'assimilative capacity' approach is being utilized to prevent deterioration of 'pristine' ecosystem. CONCEPTUAL FRAMEWORK OF ENVIRON-MENTAL MANAGEMENT STRATEGIES FOR YUGOSLAVIA: THE CASE OF THE ADRIATIC

Institut Rudjer Boskovic, Zagreb (Yugoslavia). Center for Marine Research.

V. Pravdic.
Marine Pollution Bulletin MPNBAZ, Vol. 23, p

Descriptors: \*Adriatic Sea, \*Coastal zone management, \*Environmental impact, \*Environmental

monitoring, \*Yugoslavia, Economic aspects, Economic development, Enclosed seas, Future planning, Legal aspects, Regional development, Regulations, Resource allocation.

The Adriatic is a narrow, semi-enclosed basin of the Mediterranean Sea, stretching deeply into the central part of the European continent. Developmental pressures are particularly sensitive in all semi-enclosed seas, and the case of the Adriatic Sea is no exception. The conceptual basis of an environmental management blueprint rests on the principle of integrated socio-economic, technological and physical planning with the environmental capacity concept as an environmental protection capacity concept as an environmental protection regulatory measure. The European continent has experienced three phases of strategies of environexperienced three phases of strategies of environ-mental management and protection: various laws and regulations relying on restrictions, prohibi-tions, and penalties for violation (polluter-pays-principle); the first phase combined with economic incentives to encourage pollution prevention and control; and comprehensive environmental man-agement, based on anticipatory measures and on allocation of resources. The implementation of new ideas in marine environmental management applied to semi-enclosed seas such as the Adriatic new ideas in marine environmental management applied to semi-enclosed seas such as the Adriatic will become possible with an effort in strategic planning of future development. The drafting of a long-term plan in Yugoslavia can be considered a test as to whether the conceptual framework of comprehensive environmental, economic, social and technological development can be harmonized into a viable strategy for a semi-enclosed sea. ENVIRONMENTAL ACTIVISM IN THE SAN FRANCISCO BAY ESTUARY.

San Francisco Estuary Project, P.O. Box 2050, Oakland, California.

M. W. Monroe.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 607-611, 1991. 23 ref.

Descriptors: \*Conservation, \*Environmental moni-Descriptors: "Conservation, 'Environmental moni-toring, "Estuaries, "Public participation, "San Francisco Bay, "Water resources management, Agriculture, Cooperation, Drinking water, Human population, Industrial development, Oil spills, Tourism.

Within the San Francisco Bay Estuary (SFBE) basin is a large urban population that is relatively sophisticated in its concern about environmental sophisticated in its concern about environmental groups are working to protect and enhance the Estuary and its resources, and they articulate public concerns regarding the Estuary and influence the formulation and implementation of government policies and programs. The SFBE is the most modified again, server in the lighted States emphasized for cies and programs. The STDE is the most modified major estuary in the United States, supplying 40% of the State's drinking water, as well as water for agriculture and industry, and supports commercial and sport fisheries. Respondents to a questionnaire mailed to resource managers, elected officials, scientists and public interest groups indicated that the four most important environmental problems are four most important environmental problems are wetlands filling, habitat loss, toxins, and freshwater diversion. Some of the more recent projects include the development of Cullinan Ranch, Harbor Bay Isle, the control of the Shell Oil Spill, Unocal, and dredging in San Francisco Bay. Through individual efforts and in coalitions, the environmental groups are successful largely because they represent the sentiments of a large portion of the public, and because they are able to form cooperative working relationships with a variety of interests. If recent trends continue, the environmental community's influence on the attitudes and actions of the public, lawmakers, and regulators will strengthen public, lawmakers, and regulators will strengthen the Estuary's protection. Toga River flows through a densely urbanized area of the city of Kobe before emptying into the Port of Kobe in the Seto Inland Sea. The river has Port of Kobe in the Seto Inland Sea. The river has flooded many times during heavy rains in the past and present, and the river bed and the embankment are covered with concrete. People living along the river formed the Group to Protect the Toga River in 1977, with the aim of protecting the river in their neighborhood and restoring it to a more aesthetic river through their own efforts. The group has held waterside classrooms, aimed mainly at children, cleaned up the river, and communicate with similar groups in order to exchange and ed with similar groups in order to exchange and put into practice new activities aimed at preserving water quality. Descriptors: \*Environmental monitoring, \*Environmental policy, \*Public participation, \*Water pollution control, Domestic wastes, Education, Environmental effects, Industrial wastes, Training.

Although industrial drainage is regulated by law in Japan, no regulations exist for domestic drainage.

### **Group 5G-Water Quality Control**

Waterside classes were held as a part of environmental education. Conditions necessary to promote waterside classes in a community are the establishment of a methodology, the training of leaders, and the preparation of teaching materials. Between 1984 and 1989, 66 classes were held with the participation of 3494 local community members. Trained leaders are indispensable to develop the movement to protect the water environment, and at the same time, networks have to be formed for movement to protect the water environment, and at the same time, networks have to be formed for the leaders. Functional leaders are taught the methods of biological examination of aquatic life and practical methods to improve the water environment at the home level. Through this community organization, the citizens gain a better understanding of the threat to the environment caused by domestic drainage. Grunone, PTT. by domestic drainage. The U.S. Environmental Protection Agency is using collaborative problem solving and consen problems in the building to address environmental problems in the nation's estuaries. The National Estuary Program establishes management conferences to develop and implement a comprehensive conservation and ement plan for estuaries of national significance. Representatives of federal, state, and local governme governments, the academic and scientific commu-nities, and the public and private sectors are asked to agree on the most important problems and the corrective action needed. The comprehensive plan recommends priority corrective actions and com-pliance schedules addressing point and nonpoint sources of pollution to restore and maintain the chemical, physical and biological integrity of the estuary. An important component of public in-volvement in the National Estuary Program is citizens' volunteer monitoring. Volunteer monitor-ing data is collected and used to meet a number of different water quality management objectives. Ennts, the academic and scientific commuing data is collected and used to meet a number of different water quality management objectives. Enforcement and compliance monitoring programs require quality assured and quality controlled data. Citizen monitoring provides data to meet these objectives, plays a key role in building public support for action, and ultimately creates the will to accomplish water quality improvement and other environmental goals. Citizen volunteers can augment monitoring programs already in existence at federal, state, and local levels. Mobilization of citizen volunteers permits the collection of data that would not be available through conventional methods. (Author's abstract) W91-10590

mentation, Suspended sediments, Tidal range, Tides, Transparency, Water treatment, Wave

Polluted sea water can be purified by a rubble mound breakwater. The sea water which sur-rounds the breakwater undergoes sea wave aer-ation and contact oxidation. The breakwater acts ation and contact oxidation. The breakwater acts as a sedimentation pond or oxidation lagoon. The volume of purified sea water is dependent on sea water area and tidal range difference. Generally 200,000,000 cubic m purified water is produced each day. When tested in an experimental hollow in Osaka Bay, in July, the purification system improved transparency from 60 to 170 cm, turbidity from 0.56 to 0.2 mg/L, suspended sediments from 6.06 to 4.6 mg/L, and COD from 4.64 to 3.73 mg/L. Under red tide conditions, the breakwater diluted the water, decreasing nitrogen and phosphorus, and reducing red tide. The breakwater, after initial installation, requires little additional cost, because energy is drawn from the waves and tidal ebb and flow. (Brunone-PTT) W91-10596

TREATMENT AND DISPOSAL STRATEGIES IN GREECE.

Greece lies on the northeastern shore of the Mediterranean Sea, a closed sea with a low water exchange rate. The length and shape of the coasts, the geographic distribution of the population and economic activities, as well as the terrain relief, create many problems with coastal and marine pollution. Saronoicos Gulf and Thermaikos Gulf pollution. Saronicos Guit and Thermakos Guit receive urban runoff and domestic sewage, Pagassitilos Gulf receives municipal sewage and agricultural pollution, and Amvrakikos Gulf receives multiple domestic and industrial waste. To determine the optimal restoration plan, studies of each area were carried out, with problems listed and soluwere carried only, with proteins instea and soft-tions proposed. The physical environment was de-scribed and the local economic structure defined. Existing water supply and sewer systems were mapped. Population trends were estimated, as well as existing and future pollution loads. Based on the collected data, a preliminary prediction of the col-lection, transport, treatment and disposal works. lection, transport, treatment and disposal works was made. The impact of the sewage disposal was investigated for sea disposal. The construction cost of treatment and disposal works depends on the degree of the treatment, the population served, and the local conditions. (Brunone-PTT) W91-10598

Along the southern coast of France are located pproximately fifteen lagoons, separated from the channels, These lagoons are natural zones allowing economic, recreational and tourist activities. Pollueconomic, recreational and tourist activities. Pollu-tion in these areas originates from industrial dis-charge, agricultural runoff from vineyards, shell-fish farming, and lower sanitation with increased tourist traffic. Water regulations about building limits and environmental standards require pollu-tion control on both a national and a municipal basis. Funding has been provided to fight pollution increases. Public and private initiatives have com-bined economic development and environmental protection. Improvements of the sanitation system around the lagoons have been implemented. A national reserve was erected in 1975 to preserve national reserve was effected in 1973 to preserve the environment and to develop scientific research projects on an area of 32,500 acres of protected and. The natural regional park of Camargue was created on 200,000 acres of lagoon area. (Brunone-PTT) W91-10611

A single-hit exponential model and a beta-distributed 'infectivity probability' model were used to evaluate the potential health risks from drinking water containing low levels of protozoan cysts and viruses, respectively. The models were based on dose-response curves developed from human feeding studies and assumed consumption of 2 L/day. The U. S. Environmental Protection Agency has accounted that one infection/10 000/vers is an accounted that the infection/10 000/vers is an accounted that the counter of the c A single-hit exponential model and a beta-distributsuggested that one infection/10,000/year is an acceptable risk for infectious agents acquired through potable water. Based on this risk, acceptable levels of viruses and cysts were determined using the probability models. Thus poliovirus and rotavirus levels should not be more than 0.1 and 0.3 pfu/ 100L respectively per day. Giardia levels should be below 0.2 cysts/100L. To achieve an annual risk of 1:10,000, the geometric average should not exceed 0.001 organisms/100L. As monitoring treated water for these levels would be difficult, source waters may be monitored. Geometric average of 1000 organisms/100L respired 1000L respired 100 ages of 1-100 organisms/100L require 3-5 logs of treatment reduction to achieve the 1:10,000 risk. The risk models for viruses and protozoa can be used to evaluate the occurrence of pathogens in

source water and determine the appropriate treatment needed to obtain specific levels of safety for drinking water. (See also W91-10612) (Author's abstract) W91-10619

PUBLIC HEALTH CRITERIA FOR THE AQUATIC ENVIRONMENT: RECENT WHO GUIDELINES AND THEIR APPLICATION.

World Health Organization, Geneva (Switzer-land). Div. of Environmental Health. R. Helmer, I. Hespanhol, and L. J. Saliba. Water Science and Technology WSTED4, Vol. 24, No. 2, p 35-42, 1991. 1 fig, 4 tab, 16 ref.

Over the past decade, the World Health Organiza-tion has developed a series of microbiological guidelines covering different aspects of the aquatic environment. Transmission pathways of human pathogens from their fecal origin back to man via drinking water, bathing waters, shellfish, and sewage-treated crops were investigated and epide-miology-based health criteria established. The total and fecal coliform guideline values for drinking water are generally complied with in urban water supplies but are difficult to meet in rural areas of developing countries. The Mediterranean serves as the major study area for assessing health risks from bathing in coastal waters and from the consump-tion of shellfish eaten uncooked. Wastewater reuse tion of shellfish eaten uncooked. Wastewater reuse for crop irrigation is rapidly expanding due to water shortages but poses health risks to farm workers and consumers. New guidelines for control of helminths were recently issued by a WHO Scientific Group. The predominant agent of concern varies widely among transmission pathways. Viruses are of prime importance in drinking water because of diarrhea, but they are of least concern for wastewater reuse where helminths are of for wastewater reuse, where helminths are of prime concern. Closely linked to the pathogen of concern is the choice of indicator organisms for monitoring and control. It is concluded that, especially in the control of the control o cially in developing countries, the prescription of effective treatment methods may prevent pathogen transmission more effectively than the often unreliable effectives. able enforcement of regulatory standards. The Public Health Laboratory Service has been distributing simulated water samples for quality control of bacterial analysis in the United King-dom since 1986. To assess whether a laboratory is a 'poor performer' it is necessary to observe results a poor performer it is necessary to observe results from a series of samples and see whether they report 'tail-end' results more often than would be expected by chance. The statistical assessment is made using the nonparametric method of Cochran's Q test, which looks at the scatter of binary (+/-) data in a two-way table and searches for ran's Q test, which looks at the scatter of binary (+/-) data in a two-way table and searches for nonrandomness. This test avoids any need to assume that the results are Normal, log-Normal, or Poisson. The null hypothesis that low 'tail-end' counts are occurring at random throughout the participating laboratories can be tested; the same procedure can be done with high 'tail-end' counts. A laboratory is said to have succeeded (+) with a particular sample if its count is greater than or equal to the 'tail-end' cutoff point, and is said to have failed (-) if it is less than that value. Participants are sent a copy of the assessment, highlighting their position. If the Q statistic is significant, then it should be pointed out that 'poor performance' has been demonstrated. The test is applicable only to laboratories that have returned the results for the full series of specimens. A laboratory that fails to send in results because they did not seem satisfactory has in fact passed judgment on itself. (See also W91-10612) (Doria-PTT)

SURVEILLANCE SOLUTIONS TO MICROBIO-LOGICAL PROBLEMS IN WATER QUALITY CONTROL IN DEVELOPING COUNTRIES.

B. J. Lloyd, and J. K. Bartram. Water Science and Technology WSTED4, Vol. 24, No. 2, p 61-75, 1991. 6 fig, 5 tab, 8 ref.

Descriptors: \*Bacterial analysis, \*Chemical analysis, \*Developing countries, \*Microorganisms, \*Public health, \*Quality assurance, \*Water analysis, \*Water pollution control, \*Water quality monitoring, Indonesia, Inspection, Peru, Risk assessment, Surveys, Thailand, Tracers, Water pollution sources, Water treatment.

Many developing countries are failing to apply standard water quality control methods. To achieve necessary improvements, the limitations in conventional microbiological and chemical quality control must be recognized. In the search for simpler and cheaper methods, inaccurate and spurious results are being reported in at least 10 countries in results are being reported in at least 10 countries in the Southeast Asian and Pacific regions. An integrated surveillance strategy for progressive im-provement is suggested, consisting of the following steps: area selection and basic inventories; timetabling of inspection visits; diagnostic sanitary surveys; bacteriological and chemical analysis; identi-fication of potential sources of pollution; confirma-tion that contamination is occurring; special tracer tion that contamination is occurring; special tracer studies; identification of pollution sources; consoli-dation and classification of results of diagnostic surveys; formulation of prioritized remedial action strategy; establishment of routine monitoring pro-gram; and implementation of routine monitoring gram; and implementation of routine monitoring and risk assessment program. The basic methodol-ogy and philosophy of this program have been implemented successfully in pilot projects in Peru, Indonesia, and Thailand. However, there are inad-equacies in the system, including the applications. equacies in the system, including the equal weighting of different points of risk, as well as the bacteriological grading and sanitary inspection procedures. ### Water Quality Control—Group 5G

The Commencement Bay/Tacoma site is a 190 acre industrial/municipal landfill located in Pierce County, Tacoma, Washington. The landfill is operated by the City of Tacoma Refuse Utility and is surrounded primarily by residential development and open land, with some commercial and industrial development. An aquifer beneath the site provides drinking water to the Town of Fircrest and the City of Tacoma, both of which have wells near the landfill. The Tacoma landfill began operations in 1960, to date, about 4 million tons of refuse have been deposited at the landfill to depths of 20-80 ft. Although the landfill does not accept hazardous wastes for disposal, it did receive wastes in the 1960s and 1970s that have since been designated as hazardous substances. Investigations have indicathazed to the statement of the substances. Investigations have indicathazed to the substances. Investigations have indicathazed to the substances. The Commencement Bay/Tacoma site is a 190 1908 and 1970s that have since ocen designated as hazardous substances. Investigations have indicated that the groundwater is contaminated with volatile organic compounds (VOCs). A field survey was initiated to evaluate the extent of off-site gas migration, and based on this survey a gas site gas migration, and based on this survey a gas extraction system was constructed to extract, collect, and combust the gas. Gas samples collected at the landfill revealed high levels of VOCs. The primary contaminants affecting the groundwater and surface water are VOCs including benzene, toluene, and sylenes. The selected remedial action for this site includes: construction of a cap on the landfill with runoff directed to appropriate storm or sanitary sewers, and installation of a gas extracor sanitary sewers, and installation of a gas extrac-tion system and gas probes to monitor methane gas production; installation of a groundwater pump and treatment system with discharge of treated water to a local creek or the publicly owned treatment works and alternate water supply if needed; and groundwater and surface water mo toring. The estimated present worth cost for this remedial action is between \$21,015,000 and \$23,418,000. (Author's abstract) W91-10711

TRONICS (AMENDMENT), NC. Environmental Protection Agency, Washington, DC. Office of Emergency and Remedial Response. Available from the National Technical Information Service, Springfield, VA. 22161, as PB90-114646. Price codes: A05 in paper copy, A01 in microfiche. Report No. EPA/ROD/R04-89/049, April 1989. 71p, 6 fig, 4 tab, 7 append.

Descriptors: \*Cleanup operations, \*Groundwater pollution, \*Hazardous wastes, \*North Carolina, \*Superfund, \*Water pollution sources, Costs, Explosives, Monitoring, On-site waste disposal, Organic compounds, Path of pollutants, Solvents, Waste capping, Water treatment.

This Record of Decision (ROD) amends the April 5, 1988, Chemtronics ROD which included an incorrect calculation regarding the chemical quality of the groundwater. The Chemtronics site is an active waste disposal facility located in a rural area of Swannanoa, North Carolina. Approximately 10 acres of the site were used for waste disposal facility in the control of the site were used for waste disposal facility in the control of the site were used for waste disposal facility. operations. Records indicate the presence of 23 individual on-site disposal areas (DAs) which are grouped into six discrete areas. Waste materials grouped into six discrete areas. Waste materials and solvents generated in the production of the chemical warfare agent 3-quinuclidinyl benzilate (BZ) and the tear gas agent o-chlorobenzylidene malonitrile (CS), were placed in 55 gallon drums with a neutralizing solutions, and then buried onsite in trench-type landfills. From 1971 to 1979, pits and trenchs were constructed, as needed, for the disposal of solids wastes, rocket motors, explosive wastes, spent acid, and various organic wastes. In 1980, the State ordered Chemtronics to discontin all on-site discharges, and the pits were subsequently backfilled. In September 1984, two drums were sampled because they were suspected of containing wastes from the production of BZ. Although no BZ was found, EPA initiated ann imme-

### Group 5G-Water Quality Control

diate removal of these drums in January 1985 due to heightened public awareness of the site. The original remedy (soil fixation-stabilization-soildification, capping) was selected due to the concentration levels of the contaminant benzylic acid a benzophenone found in the groundwater downgradient of one disposal site. However, a transcription error was discovered in the analytical results for this groundwater sample. The laboratory reported the concentration as 470 mg/L instead of 470 microgm/L. Subsequent sampling verified that the correct concentration was in the 0-470 microgm/L range. Therefore, EPA elected to change the source control remedial action for the site to capping only. The primary contaminants of concern affecting the soil, sediment, groundwater and surface water are volatile organic compounds including benzene, toluene, pesticides, and explosives. The selected remedial action for this site includes multi-layer capping; groundwater pumping and treatment using air stripping, carbon adsorption; and monitoring. (Lantz-PTT) W91-10713.

Descriptors: \*Cleanup operations, \*Groundwater pollution, \*IBM (San Jose) Site, \*Path of pollutants, \*Superfund, \*Water pollution sources, Acctone, Aquifers, California, Drinking water, Groundwater movement, Organic compounds, Soil contamination, Solvents, Toluene, Trichloroethane, Volatile organic compounds, Waste storage, Water treatment, Xylenes.

International Business Machines (IBM) has owned and operated a facility in San Jose, California, since December 1956 using organic chemicals including trichloroethane (TCA), acetone, xylene, and petroleum naphthas. The organics have been handled and stored on-site in drums, and aboveground and underground tanks. In addition, waste organic solvents were stored in concrete or steel underground tanks or drums; however, the concrete tanks were designed only to store organic wastes. In October 1980, while excavating tanks in Tank Farm No. 1, IBM discovered soil contaminated with organics. Furthermore, investigations in November 1981 revealed extensive groundwater contamination. The groundwater plume extends more than 3 mi northwest and is more than 180 ft in depth. Fourteen active or potentially active water supply wells are downgradient to the plume; however none of these public wells have been found to contain volatile organic compounds (VOCs) above State and Federal drinking water standards. Nineteen sources of soil and groundwater contamination have been identified including and tank and pipeline fitting failures. Activities to prevent further solvent migration from the IBM source areas have been conducted including removing underground storage tanks which were replaced with above-ground tanks, and excavating more than 23,000 cu yd of contaminated soil. Interim remedial measures begun in November 1982 to clean up the plume have included off-site and onsite groundwater extraction with discharge of untreated groundwater to storm drains. The primary contaminants of concern affecting the soil and groundwater are VOCs including TCA, toluene, and xylenes; and other organics. The selected remedial action for this site includes on-site soil vapor extraction on-site sproundwater extraction with discharge of untreated groundwater to storm drains. The primary contaminants of concern affecting the soil and groundwater and off-site discharge to surface water after the reuse capacity of the aquifer is exhausted. Remedial acti

USING OIL SPILL DISPERSANTS ON THE

The Commission on Engineering and Technical Systems of the National Research Council, was charged to assess the state of the knowledge and practice about the use of dispersants in responding to open ocean oil spills. This assessment will guide federal and local governments and industry in both the United States and Canada, in defining the role of dispersants in oil spill response and implementing the use of dispersants. The committee recommends that dispersants be considered as a potential first response option to oil spills, along with other response options. Implementation of this recommendations must consider spill size, logistical requirements, contingency planning, equipment and dispersant performance and availability, appropriate regulations, and personnel training. Sensitive inshore habitats, such as salt marshes, coral reefs, sea grasses, and mangroves, are best protected by preventing oil from reaching them. Dispersion of oil at sea, before a slick reaches a sensitive habitat, generally will reduce the overall and particularly the chronic impact of oil on many habitats. This has been shown by research studies that compared the biological effects of untreated and dispersed oil released on water over the intertidal or immediate sub-tidal zones at Baffin Island (arctic); Long Cove, Maine (north temperate); and Panama (trop-ical). Although these studies generally showed that dispersed oil caused less chronic environmental that additional ecological studies be conducted, under controlled or naturally established water circulation regimes in shallow environments, to help define the conditions under which dispersant use will be effective and environmentally safe. Because the principal biological benefit of dispersant use is prevention of oil stranding on sensitive shorelines, and because dispersability of oil decreases rapidly with weathering, prompt response is essential. Therefore, the committee recommends that regulations and contingency planning make rapill to establish dispersability in cases of doubt. (

SUPERFUND RECORD OF DECISION: DELA-WARE SAND AND GRAVEL, DE.

Environmental Protection Agency, Washington, DC. Office of Emergency and Remedial Response. Available from the National Technical Information Service, Springfield, VA 22161, as PB89-206205. Price codes: A05 in paper copy, A01 in microfiche. Report No. EPA/ROD/R03-88/048, April 1988. 80p, 7 fig, 8 tab, append.

Descriptors: \*Cleanup operations, \*Delaware, \*Delaware Sand and Gravel Site, \*Superfund, \*Volatile organic compounds, \*Water pollution sources, Benzenes, Chromium, Excavation, Groundwater pollution, Incineration, Lead, Monitoring, Organic compounds, Phenols, Polychlorinated biphenyls, Polycyclic aromatic hydrocarbons, Site remediation, Toluene, Waste capping, Waste disposal, Xylenes.

The Delaware Sand and Gravel (DSG) site is a 27 acre inactive industrial waste landfill located in New Castle County, Delaware. It is bordered by Army Creek to the west, and Army Creek and wetlands to the north. Underlying the landfill is the Potomac Aquifer, which is accessed about 1.25 miles south of the site and used as a public water

source. From 1968-1976 the site accepted household construction wastes and approximately 7,000 drums containing liquids and sludges from perfume, plastics, paint, and petroleum refining processes. The primary contaminants of concern affecting the soil and groundwater are VOCs including benzene, toluene, and xylenes, other organics including PCBs, PAHs, and phenols, and metals including chromium and lead. Selected remedial action for the site includes: excavation and on-site mobile incineration of approximately 36,000 tons of contaminated soil and wastes from the Drum Disposal and Ridge areas, with on-site or off-site disposal of residual ash and grading and revegetation of excavated areas; removal and off-site disposal of all surface debris material from the inert area, followed by capping, and construction of a cap over the Grantham South area; groundwater pump and treatment with discharge to Army Creek; and groundwater monitoring. The estimated present worth cost for this remedial action is \$24,944,000. (Lantz-PTT)

SUPERFUND RECORD OF DECISION: PESSES CHEMICAL, TX.

Environmental Protection Agency, Washington, DC. Office of Emergency and Remedial Response. Available from the National Technical Information Service, Springfield, VA 22161, as PB89-229561. Descriptors: \*Cleanup operations, \*Heavy metals, \*Pesses Chemical Site, \*Soil contamination, \*Superfund, \*Texas, Batteries, Cadmium, Costs, Excavation, Lead, Nickel, Site remediation, Sludge, Waste capping, Waste disposal.

The 4.2-acre Pesses Chemical Company site is located in Tarrant County, Ft. Worth, Texas. The site is situated in a light industrial and commercial area with an estimated 19,500 people residing or working within a one mile radius. In June 1979, the Presses Company began operations to reclaim cadmium and nickel from dry cell batteries and metal sludges. During July and August 1979, excessive cadmium emissions were investigated by city and state air pollution control offices. Cadmium emissions were measured as high as 2,900 percent above permit limits. In January 1981, the site operations were discontinued. In March 1983, a grass fire at the site resulted in toxic cadmium oxide fumes. Approximately 1,500 deteriorating drums containing heavy metal sludges, powder, and empty battery cases remained on-site. Heavy metals contamination from airborne dust and surface water runoff are the main potential threats at the site. Two sumps in the southern portion of the site contain 1,914 gallons of liquid contaminated with cadmium and nickel. Primary contaminated of contaminated off-site soil and wastes; consolidation with on-site contaminated soil with installation of a concrete cap placed at the south warehouse and office building; and a clay cap placed on the south field. Waters will be treated and discharged into the sewer system. The estimated present worth cost for this remedial action is \$1,200,000, with annual operation and maintenance costs of \$7000. lution, Heavy metals, Leaching, Lead, Polycyclic aromatic hydrocarbons, Revegetation, Site remedi-ation, Sludge, Soil contamination, Volatile organic compounds, Waste disposal.

The Iron Horse Park site is a 552-acre industrial complex and railyard located in North Billerica, Massachusetts. The site includes manufacturing and railyard maintenance facilities, open storage areas, landfills, and wastewater lagoons. A long history of activities at the site has resulted in history of activities at the site has resulted in contamination of soil, groundwater, and surface water. The site was divided into several separate problem areas. This ROD addresses the cleanup of the Boston and Maine Wastewater lagoons (B and M Lagoons) and surrounding area. The lagoons have been receiving untreated industrial and sanitary wastewater from the manufacturing and railyard maintenance facilities since 1915. The lagoon area consists a North and South lagoon currently receiving wastewater. receiving wastewater, an overflow lagoon, one inactive lagoon used until 1954, and an empty lagoon which was never used. The lagoons contain approximately 7,800 cu yds of soil and sludge contaminated with volatile organic compounds contaminated with volatile organic compounds (VOCs), low level polycyclic aromatic hydrocar-bons (PAHs), and metals. In addition, approxi-mately 20,000 cu yds of soil and sludge dredged from the lagoon bottoms are contaminated with from the lagoon cottoms are contaminated with low levels of organics and metals. The piles of dredged materials and the sludge in the lagoons are considered to not contribute significantly to groundwater contamination. The primary contaminants of concern affecting the soil, sludge, and debris are VOCs, organic PAHs, and metals including arsenic and lead. Selected remedial action for the site includes: excavation and on-site biode-gradation of contaminated soil and sludge with residual disposal to the lagoon area followed by covering with a clean soil cover and revegetation; covering with a clean soil cover and revegetation; and decontamination of the lagoon piping system and pumps. The estimated capital cost for this remedial action is \$2,273,000 with present worth operation and maintenance costs of \$47,000. (Lantz-PTT) W91-10719

SUPERFUND RECORD OF DECISION: SOUTH VALLEY (PL-83), NM. Environmental Protection Agency, Washington, DC. Office of Emergency and Remedial Response. Available from the National Technical Information Services Servicefield, VA. 21161, pp. 1899 20160. Service, Springfield, VA 22161, as PB89-204812. Price codes: A05 in paper copy, A01 in microfiche. Descriptors: \*Cleanup operations, \*New Mexico, \*Site remediation, \*South Valley Superfund Site, "Superfund, "Water pollution sources, Air stripping, Extraction, Groundwater pollution, Heavy metals, Methylene chloride, Military reservations, Solvents, Tetrachloroethene, Volatile organic compounds.

The former Air Force Plant 83/General Electric The former Air Force Plant 83/General Electric Operable Unit (PL-83) is a portion of the South Valley Superfund site in the Albuquerque Municipal Water Well known as San Jose No. 6. The General Electric property is located in the western portion of the site, and the south valley site is situated in an industrial area. Contaminants of the South Valley site consist mainly of industrial solvents. The majority of the GE site is covered with paying or buildings. Three areas of contamination have been identified at the site: four hazardous waste storage areas which were used for chemical storage; the north parking lot (a former dirt parking lot which was sprayed with oil as a dust control measure); and the DWB-2 area which con-tains methylene chloride and freon contamination. The volume of contaminated soils is estimated to be 36,000 cu yds. In addition to soil contamination, groundwater contamination occurs at depths of up to 160 ft. The primary contaminants of concern affecting the groundwater and soil are volatile organic compounds (VOCs) including PCE, and metals. Selected remedial action for this site includes: installation of soil vapor extraction wells; extraction of soil water vapor under vacuum; in-stallation of groundwater extraction wells in both the shallow aquifer and the deeper zone; treatment of extracted groundwater with air stripping followed by carbon adsorption and reinjection of treated water into the aquifers; and further definition of groundwater contamination through installation and sampling of additional monitoring wells. The estimated present worth cost for soil remediation is \$1,820,000. No figures are given for the groundwater remedial action. (Lantz-PTT)

FISCAL YEAR 1988 SUPPORTED LIQUID MEMBRANE DEVELOPMENT REPOR Westinghouse Hanford Co., Richland, WA K. M. Hodgson.

Descriptors: \*Groundwater pollution, \*Membrane processes, \*Supported liquid membranes, \*Uranium, \*Water pollution treatment, \*Water treatment, Acids, Laboratory methods, Membranes, Organic compounds, Polypropylene, Pore size, Tempera-

Supported Liquid Membranes have been proposed as a potential process for removing uranium and other contaminants from groundwater. Supported other commands from groundwater. Supporters liquid membrane technology is an emerging technology that has the potential to remove dilute components from a feed stream and concentrate them into a strip solution. A liquid membrane is an organic compound that forms a barrier between the feed stream and the strip stream in a solvent extraction process. A supported liquid membrane is a membrane in which the organic extractant is absorbed in the pores of a microporous membrane support. Two test stands were used for testing done in FY 1988. One test strand was used to test modules, while the other was used in the demor stration of a uranium removal process developed stration of a uranium removal process developed by the Argonne National Laboratory. The models tested were hollow fiber modules containing fibers made from polypropylene. The module testing indicated that in the flow range tested, the flow rate had very little effect on the amount of acid extracted. The testing also showed that membranes on the cu. Inc testing also showed that memoranes on the smaller pore size support were more stable than the large pore size support, and that increasing the temperature increased the extraction rate but decreased the membrane stability. Descriptors: \*Legal aspects, \*Nonpoint pollution sources, \*Permits, \*Water pollution control, Agricultural runoff, Best management practices, Model studies, Settling basins, Standards, Storm runoff,

In recent years, an increasing number of states and local agencies have instituted permitting programs to control nonpoint source (NPS) water pollution. Permits are issued to both urban and agricultural NPS generators. NPS permit applications typically NPS generators. NPS permit applications typically require a range of maps and support documentation that help indicate the impact of the operation on water quality. Permit applicants rely heavily on consulting engineers to design the best management practices (BMPs) allowed in the permit. Most NPS permits conform to design standards which detail BMP specifications, rather than to performance standards which limit the amount or pollutant concentration of allowable runoff. For such a NPS permitting system to ensure water quality, howevpermitting system to ensure water quality, however, permits should include reopener clauses or

expire periodically. This would allow for modifications in response to the dynamic ambient condi-tions of receiving waters. Although permits for both agricultural and urban NPS discharges tend to require retention or detention structures, other nonstructural BMPs are increasingly included in permit conditions. The Water Quality Act's storm-water provisions and EPA's proposed regulations are primarily procedural in nature and do not stipulate the form or stringency of stormwater permits. Enforcement of NPS permits should proactively utilize inspection programs to prevent violations. Aerial surveillance can help to suppleviolations. Aerial surveillance can help to supple-ment personnel shortages. Once a deficiency is identified, the decision to initiate enforcement action should be based primarily on the potential for adverse impacts upon receiving waters. Other factors should include the extent of the deficiency and existence of past violations. There are many sociological, economic and political factors which sociological, economic and political factors which appear to influence the success of a NPS permitting program. While cost-sharing programs may enhance the effectiveness of a permitting system, most regulatory programs for NPS have actually arisen because of the absence of such nonregulatory programs. Because most NPS permitting systems have been established only recently, there is an absence of evaluation literature assessing their effectiveness either in terms of permittee complian absence of evaluation increasing assessing their effectiveness either in terms of permittee compliance or water quality impact. Yet, it appears that NPS permitting programs are becoming increasingly comprehensive and effective in their efforts to reduce runoff. (Lantz-PTT) W91-10730

STATUS OF GROUND WATER IN THE 1100
